1 PROCEEDINGS

2 (9:05 a.m.)

3 MS. SILVERSTEIN: Thank you for coming to FERC's
4 conference today. Our topic is Standard Market Design, and
5 Software To Support That In Wholesale Electric Markets.

6 I am Alison Silverstein, Advisor to Chairman Pat
7 Wood III. With me today are numerous members of FERC staff,
8 some of whom are sitting up here and some of whom are in the
9 audience and prepared to throw us hard questions as the
10 opportunity arises.

11 Let me introduce the folks who are here. We've
12 got Tom Rieley, Thanh Luong, Dick O'Neill, Bill Hederman; we
13 are joined, happily, by Phil Overholt of the Department of
14 Energy. And Marv Rosenberg of FERC. And other folks over
15 on the side who will help us as appropriate later in the
16 afternoon.

17 As you all know, but just for the record,
18 Standard Market Design, the purpose of this is to reduce
19 transactions costs and to reduce the costs of making markets
20 work and to improve their efficiency.

21 In the future, we have heard repeatedly and we
22 are hoping that it's wrong, that software will be a
23 potential impediment; that scalability will be a challenge
24 as we move to larger regional transmission organizations,
25 and that people with bad intention are trying to hurt the

1 electric industry and trying to damage the instructions and
2 the software that underlie electricity, that underlie our
3 society.

4 And so part of what we're doing in trying to get
5 a handle on what software capabilities are and what software
6 needs are is to make sure that software can support markets
7 in every way:

8 To assure their efficient operation, to assure
9 that they remain secure in their operation and they support
10 the needs of a competitive market as well as a secure
11 infrastructure.

12 We are happy to have so many vendors and so many
13 people here representing the ISOs and the RTOs and those of
14 you who make this stuff work for a living, we thank you for
15 caring about this topic and taking the time to share your
16 knowledge with us.

17 And what else do I need to tell you? The agenda
18 is in the back of the room. The bathrooms are past the
19 elevators. If you need to get up and walk around, do so.
20 We schedule long panels and we keep going, so if you need to
21 leave the room, do so. And we will walk in and out because
22 we have a lot going on today, but it doesn't mean we don't
23 care about you. So we apologize for that in advance.

24 Anything else we need to mention, Dick? Let 'er
25 rip. Okey dokey. Our first panel is on software

1 development. And these gentlemen have been kind enough to
2 roll with the punches today because we have a slightly
3 disorganized agenda and plan for what we're going to cover,
4 and part of it we're going to make up when we go along, but
5 our general format is that I'm going to ask each of them to
6 introduce themselves and their organization.

7 Then I've asked each of them to give an overview
8 with respect to major chunks of software that are needed to
9 make a market work, and then each of them is going to talk
10 for another five minutes in a prepared text, and then those
11 of us here are going to start asking questions, and we will
12 have a time for audience participation in case you've got
13 questions you want answered, and I expect that they will
14 want to respond to each other's questions and comments as
15 well as to us. So we're just going to roll with it.

16 The other thing that I need to tell you if this
17 gets long is that I have a watch, I'm not afraid to use it.
18 So if people start going on on something that doesn't appear
19 to be real focused on the topic at hand, I will try as
20 politely as I can to move us back to the issue in front of
21 us.

22 So let's start with you, Mr. Ristanovic and hear
23 about you and your organization.

24 MR. RISTANOVIC: Good morning. I'm glad to be
25 here today to talk about this important topic. My name is

1 Petar Ristanovic. I am from Siemens Energy Management
2 Information Systems from Minneapolis. My company is a
3 worldwide provider of software for electric utility computer
4 centers and energy management, distribution management
5 market systems.

6 We are in business for over 30 years if you count
7 ComtraData and Impros and Siemens and Telegear and all the
8 companies who are making Siemens Power Transmission and
9 Distribution. And we are here today to present our views of
10 how we can build software cheaper and better and make these
11 RTO ISO systems more efficient and less expensive.

12 MR. FINNEY: Hi. I'm John Finney from ABB. As
13 you probably know, ABB is a global automation and power
14 technology company serving the energy electric power
15 customers worldwide. We have about a thousand IT
16 professionals in four different countries building systems
17 to support not only central market activity but retail
18 systems and wholesale systems.

19 I hope today, in addition to helping clarify a
20 bunch of issues, we will also have the opportunity to
21 convince you of the needs for standards and integration
22 techniques that can be used to produce these systems more
23 cheaply and more reliably.

24 MR. IRISARRI: Good morning. My name is
25 Guillermo Irisarri. I represent Open Access Technology

1 International from Minneapolis, Minnesota.

2 Over the past seven years, OATI has been very
3 active in the development of computer applications to
4 support the deregulating efforts in the United States and
5 North America in general.

6 We have been very much involved with two of the
7 main systems that are used today in that support fashion.
8 One of them is the tagging system, which as you all know is
9 a real time system that encompasses the whole of North
10 America, and the second one related to the tagging system,
11 which is very pertinent to the efforts of the Standard
12 Market Design is the IDC, the Interchange Distribution
13 Calculator, which is the tool currently used in the Eastern
14 Interconnection of the United States to manage congestion.
15 And it has quite a few of the elements necessary to support
16 the development of systems such as the ones envisioned for
17 the Standard Market Design.

18 The issues related to the development and support
19 and maintenance of those systems are pertinent issues to the
20 issues that will be faced in developing each and every one
21 of the applications that comprise the Standard Market Design
22 and thus the experience that we have gathered in developing
23 those, maintaining, standardizing and using already
24 available standards in their development, will be pertinent
25 to any of the future plans envisioned for the SMD.

1 So we are very happy to be here as well and
2 looking forward to the discussion. Thank you.

3 MR. ALSAC: Good morning. My name is Ogun
4 Alsac. I am from Nexant, Inc. in charge of Power Computer
5 Applications Division. We are located in Mesa, Arizona.
6 Our division is mainly responsible for the stand-alone
7 integrated market-related software products of the company.

8 Since 1984, our group specializes in high end
9 power system software development. Over the years we have
10 developed many market-related software applications,
11 including state estimation, topology estimation, security
12 analysis, optimal power flow, which can be used for
13 congestion management, bid-based dispatch, LMP calculation,
14 preventive and corrective dispatch, voltage and reactive
15 power dispatch, financial transmission rights, rights
16 auctions and allocations, simultaneous visibility analysis
17 and maximum transfer capability.

18 Some of our software I mentioned about is used
19 worldwide in about 100 control centers in online mode and
20 most of them have been integrated with the systems of almost
21 all major EMS vendors. This puts us in a unique position to
22 share our experience in the Standard Market Design
23 discussions.

24 We are very pleased to be here on this panel to
25 express our views.

1 MR. BRITTON: Good morning. I'm Jay Britton.
2 I'm with ALSTOM Corporation. ALSTOM is a global supplier to
3 the electric utility industry, and what's most pertinent to
4 this discussion is that we're a major supplier of market
5 systems. And it's a pleasure to be here this morning.

6 MS. SILVERSTEIN: Well, it's a pleasure to have
7 you all here. Thank you very much. The first thing I want
8 to do is to get an overview of the functionality of the
9 major pieces of software that are needed to run markets.

10 And I've put these gentlemen on the spot by
11 asking each of them with no warning whatsoever to talk for
12 up to five minutes about a separate chunk of software, and
13 in most cases it is about a piece of software that this
14 company has running in one or more ISO areas.

15 So our first topic will be the functionality
16 behind an FTR software and the processes which it performs.
17 From Nexant, Mr. Alsac will be speaking. Thank you.

18 MR. ALSAC: Our company has done a number of
19 software projects. We have done what is called TCC
20 obligations for New York ISO about four years ago. This was
21 followed up by a DC model of the same point-to-point
22 obligations approach for PJM. Two years ago we were asked
23 to develop a multi-period obligations package for New York
24 ISO. This has been delivered and New York is testing this
25 multi-period software which they will change their market,

1 and also very recently we have completed a project with PJM
2 combining obligations and options.

3 MS. SILVERSTEIN: Would you be good enough to
4 walk us through what an FTR model does please?

5 MR. ALSAC: Yes.

6 MS. SILVERSTEIN: Thank you.

7 MR. ALSAC: So this gives us a lot of
8 understanding of the FTR definitions. FTR is mainly a
9 separate, not an online but a separate market system used
10 for hedging any a real time commitments and it is done in
11 terms of monthly, sometimes six-monthly. It is possible to
12 have it seasonal as well as yearly, five-yearly auction
13 periods where participants offer buy-sell bids, and these
14 bids in general can be what is called point-to-point, or in
15 some markets, also defined as flowgate bids.

16 And also recently both obligation type of FTRs
17 and option type of FTRs have been asked in different ISO
18 designs, and FTR, Financial Transmission Rights
19 calculations, should address these things.

20 And it is also possible, as I mentioned, for FTRs
21 to be a single period, like a monthly FTR for that specific
22 month, or a multi-period where it is over a number of
23 periods can be used.

24 When we look at, again, the requirements of
25 different ISOs, we see that there are specifications where

1 DC network type of models can be used. There are also
2 specifications where AC type of network models are used, and
3 for the DC network model markets, there's a concern of
4 representing losses. There's a concern of representing
5 voltage and reactor power effects. But again, it is
6 understood that this is a financial system and it doesn't
7 have to mimic exactly the actual operation of the system in
8 real time.

9 And I think this is like a brief summary of the
10 main financial transmission rights. It is also this
11 involves a couple of other calculations, and one of them is
12 simultaneous feasibility testing where initial allocations
13 are tested whether they are feasible or not. This brings a
14 problem of if they are not feasible, what to do, and that is
15 part of simultaneous feasibility analysis where how to pro
16 rata curtail the existing rights to make them feasible.

17 Also another problem associated with FTRs is
18 multi-round FTRs where it is used by many ISOs for price
19 discovery. An auction is held and results are awarded in
20 certain percentages, and everyone sees the results and they
21 keep bidding. They can continue buying and selling, so this
22 is part of the FTR problem.

23 And an intimately related issue is what to do
24 with the auction revenue rights, how to allocate FTR auction
25 revenue rights and how to do this fairly and how to get it

1 right. This is a big issue in the FTR area. And basically
2 the software. We have developed software for all these
3 components.

4 And our experience, just to summarize, is that
5 although it is one of the most computationally extensive or
6 expensive network grid analysis calculation for the existing
7 size of ISOs, it is still feasible to do these things on
8 today's existing computers.

9 MS. SILVERSTEIN: And if we were to look under
10 the hood of one of these models, what kind of computational
11 techniques would we see inside?

12 MR. ALSAC: Most probably it is DC models based
13 on linear programming techniques or AC models based on
14 nonlinear programming techniques.

15 MS. SILVERSTEIN: Thank you very much. Our next
16 discussant will be Dr. Irisarri from OATI who will talk
17 about the day ahead market.

18 DR. IRISARRI: Okay. As probably you all know by
19 now, the Standard Market Design calls for essentially three
20 types of systems. The first one was already discussed by
21 Ongun here, the FTR location.

22 Then there are two markets that we have to deal
23 with, the real time market, essentially a balancing market,
24 and the day ahead market. The day ahead market basically
25 consists in the scheduling of all the resources available in

1 the system for the next 24 hours. Typically, the result,
2 the schedules are providing starting at say the midnight of
3 a day and covers the whole 24 hours of the day, based on the
4 following considerations:

5 The participants in the markets, specifically the
6 generation participants, submit voluntary bids into the
7 system. Those bids are typically for this kind of problem
8 the day ahead market problem, are multi-part bids that
9 include the startup and shutdown costs of generating units,
10 include the energy bids, and may include bids for reserves
11 as well.

12 The outcome of this process will consist of all
13 the generating unit schedules for the next 24 hours
14 necessary to meet the demand, and it should incorporate
15 requirements such as an ability to provide bilateral
16 schedules; that is, schedules that have been prearranged
17 between two parties, as well as self-schedules for certain
18 generating units. For instance, large generating units,
19 nuclear-type units, or many large coal-fired units are
20 either prescheduled or they remain at a baseload capacity
21 during the day. Therefore, those are essentially
22 precommitted and they will not necessarily participate in
23 the day ahead market calculation.

24 Now what are the calculations for the day ahead
25 market and what are the complexities? The main calculation

1 that is used to do the resource scheduling for the day ahead
2 market as we all know is called a unit commitment. That
3 obligation has been around for many years in the electrical
4 industry at different levels and for different system sizes.
5 But now it takes a significant relevance due to the very
6 large sizes that are ambitions for the RTOs.

7 If you consider an RTO today of the size of the
8 Midwest ISO, for example, which includes in excess of 2,000
9 generating units, out of which possibly a great majority of
10 those will be participating in the day ahead scheduling
11 process, that would be a very significant size issue in the
12 solution of the problem.

13 Then you have to add to that problem the next
14 aspect which traditionally has been ignored in most unit
15 commitment development, which is the network concerns, and
16 in particular the congestion associated with the network
17 operation. Therefore, this type of unit commitment for the
18 next day is called security constrained unit commitment
19 where "security" in this case means the satisfaction of all
20 the requirements of the electrical network.

21 That is, there should not be any violations in
22 transmission flows in transmission facilities, in
23 transformer facilities, et cetera. So it should remain
24 feasible, not only for a base case condition, but also under
25 the possibility of many contingencies, where a contingency

1 would be the outage of one or more facilities, either
2 generating facilities or transmission facilities.

3 In addition, reserve requirements have to be
4 maintained for the whole system and for individual control
5 areas, in many cases, particularly in systems such as MISO,
6 which is made up of in excess of 45 or so control areas,
7 each control area has a reserve requirement of their own,
8 and the unit commitment application for the resources
9 scheduling for the next day has to satisfy the reserve
10 requirements of the whole interconnection of the whole
11 system of the whole RTO as well as the individual control
12 areas.

13 There are two main outcomes of the resource
14 scheduling problem. One of them is going to be of course
15 the schedules themselves for the generating facilities. The
16 second one of significance to the operation of the market is
17 the market signal provided to the participants, and those
18 are typically the locational marginal prices are all of the
19 buses or nodes in the system, or in some instances may be
20 grouped into zones or hubs or aggregates of various kinds.

21 So it has those two significant outcomes, as I
22 said. The schedules themselves as well as the market
23 signals, LMPs, as you -- today, some of the markets are
24 already operating basically as I have described, and the New
25 York ISO is one of those. PJM is another one that also does

1 some sort of resource scheduling. They provide exactly this
2 kind of information.

3 Now what are the tools that are needed to solve
4 these problems and what are the complexities?

24

25

1 The unit commitment and security constraint unit
2 commitment problem is typically formulated as a non-linear
3 optimization problem. In these cases, it's a non-linear
4 problem, although it may have linear constraints. It's a
5 non-linear problem for a variety of reasons.

6 First of all the bids. The objective function
7 itself, which is the total cost of operating the system, is
8 a non-linear function and some of the typical constraints in
9 the unit commitment are non-linear constraints as well.

10 In addition, it has a time factor associated with
11 it. The dispatch is done over the period of 24 hours. So
12 it adds another dimension to the problem.

13 And associated with time, of course, is the
14 operation of the generating facilities. The generating
15 facilities have to be ramped up or down according to the
16 requirements of each one of those generating facilities and
17 that has to be taken into account in the problem.

18 In addition, some of those units have a minimum
19 start-up time or a minimum shut down time. They cannot be
20 started instantaneously. They cannot be shut down
21 instantaneously and that has to be taken into account into
22 the problem.

23 The problem is typically solved as a non-linear
24 optimization problem. The algorithms that are typically
25 used to solve large scale unit commitment problems is the

1 so-called LaGrandian Relaxation which is familiar to most
2 operation research people here, and it also has an element
3 of dynamic programming within it where the LaGrandian
4 Relaxation process consists of formulating a primal problem
5 which is decomposed into individual problems for each of the
6 generating units.

7 Each individual problem is solved as a dynamic
8 programming problem for the next 24 hours. And then there
9 is an external loop which is called the LaGrandian
10 Relaxation Loop that adjusts the penalty factors in this
11 case which ultimately are actually the data needed to
12 compute the locational marginal prices.

13 So in a nutshell, that's what I learned in
14 college a few years back --

15 (Laughter.)

16 MR. IRISARRI: -- and we at OATI have been very
17 interested in all of the aspects of the standard market
18 design and have developed tools already to support those
19 including the auction and including the real time, and
20 particularly we are very interested in the day-ahead market
21 as well.

22 Thank you very much.

23 MS. SILVERSTEIN: Thank you.

24 Next to talk about the real time market will be
25 Mr. Britton with Alstom.

1 MR. BRITTON: Well I think I am going to try to
2 stay at a little higher level because I don't want to go
3 that deep.

4 The real time market essentially is required in
5 systems because whatever you do up front to try to arrange
6 the schedules, the actual load that occurs at a particular
7 time is not precisely predictable. And you have some last
8 minute adjustments to do and the electrical system will
9 take care of that pretty much by itself. But you need
10 something to figure out in the context of markets what's
11 actually happened and who owes what to whom for those
12 corrections.

13 So the start of the real time market is a state
14 estimation. I understand somebody else is going to talk
15 about state estimation but state estimation gives you the
16 current state of the power system, and that's the starting
17 point that you need for figuring out what's going on.

18 The state estimation serves as the basis for
19 what's called "security constrained dispatch" and that
20 allows you to look at whether there's congestion in the
21 system and eventually calculation the locational marginal
22 prices in the network that actually exists.

23 On the basis of those results, according to the
24 rules of the market, the accounting of who did what to whom
25 is made. Thank you.

1 MS. SILVERSTEIN: Showing unusual restraint, you
2 clock in as the fastest performer here.

3 (Laughter.)

4 MS. SILVERSTEIN: But I'm going to give you
5 another chance when we get into the mountains and see if you
6 want to take more time.

7 And next to talk about the State Estimator, we
8 have Mr. Finney with ABB.

9 MR. FINNEY: Thanks. Well, of the three
10 components we're talking about here, the day-ahead
11 scheduler, the real time scheduler, and the State Estimator.
12 This is the black box that does not have immediate
13 transparency to the market participant himself, because when
14 we deal with both day ahead scheduling and real time
15 scheduling, we're integrating the optimization of the bids
16 and the market itself and has an interface. So the State
17 Estimator is the least understood but has a very important
18 role. When we start with day-ahead scheduling, we use as
19 our network, our network model since the data that comes
20 from a database which says this is what we think the grid
21 will look like tomorrow based upon what we think it looks
22 like today. And that's fine because the next day, when we
23 go to do the real time scheduling, we have the opportunity
24 to update that network model.

25 Now there's an immediacy required now that was

1 not there in the day-ahead schedule. So rather than using
2 static data, we used a computer program called a State
3 Estimator to tell us exactly what the grid looks like
4 exactly now when we begin the clearing of the real time
5 market.

6 Now the technical challenge here is we receive
7 our knowledge about what the grid looks like from two
8 different sources. One is what we think it looks like from
9 what lines we know to be in service, what transformers we
10 know to be in service, and then we receive real time
11 telemetry which is piped in from transducers all across the
12 system. Way back in graduate school, we learned a basic
13 set, very simple actually, of non-linear equations that
14 relate voltage and angle to real and reactive power flow.
15 So when we have all of this telemetry, there is a set of
16 equations that in principle we should be able to solve that
17 will tell us exactly the state of the grid. And when we did
18 the homework problems back in college, the answers always
19 worked out just fine and we went to the next problem.

20 Somebody has to go there. So, and if it were as
21 simple as that, this question wouldn't have come up today
22 because the problem is is that transducers are notoriously
23 bad, right? Data gets, in the same way that when reports
24 work their way up to you messages get scrambled exactly he
25 same thing. Bad data comes in from the network and the

1 State Estimator is responsible for deciding, okay, I have
2 bad data. How do I get a good estimate of what the grid
3 looks like from bad data.

4 Now this is not a new problem. This is the
5 problem that everyone here has been solving in the industry
6 in the context of EMS SCATA systems for quite some time.
7 The problem that we see now, when we look at real time
8 scheduling markets is availability of good answers of this
9 data. Convergence of State Estimators is not guaranteed.
10 If the data is too bad or if the telemetry fails, or for a
11 variety of other minor reasons, we will not get good answers
12 out of the program.

13 And for years, you know, I think standards in the
14 industry is if you could converge 95 percent of the time,
15 that was fine; 99 percent of the time, that was fine. Now
16 why was that? In the past, this data was being used pretty
17 much exclusively by the control center operator himself to
18 maintain the reliability of the grid and if we want a couple
19 cycles or minutes or hours with the State Estimator not
20 performing fine. It wasn't a big deal because we could keep
21 the grid reliable. But in the modern real time scheduling
22 applications, we can't have no data coming into the program
23 as we clear bids on a five-minute or hourly basis. So the
24 challenge that I think prompts the question today is are we
25 prepared to modify our State Estimators so that we can

1 recover from the previously assumed normal situation of it's
2 okay not to converge all the time, and can we guarantee that
3 we won't let down the market systems as we head into real
4 time scheduling.

5 And the answer here fortunately is yes because we
6 ran into this occurrence of course in our deployment at
7 Ontario IMO and were forced to sit back, scratch our heads,
8 and perform, you know, some fairly significant modifications
9 to the estimator program, which would guarantee that when we
10 couldn't get a perfect answer to feed into the real time
11 scheduling application, we could get one that would allow
12 the market to continue to function without destroying the
13 transparency associated with good clearing price information
14 out of the algorithm. Thanks.

15 MS. SILVERSTEIN: Thank you.

16 And to talk about how all of these models and
17 software pieces are integrated together, from Siemens, Mr.
18 Ristanovic.

19 MR. RISTANOVIC: Thank you very much. I guess I
20 was lucky that this drove as closest to what they prepared.
21 All these large components plus a few others like market
22 monitoring, install capacity market, support systems,
23 complications, have to work nicely together on very large
24 systems. And that is one of the major sources of high cost,
25 high start-up costs and high maintenance costs to manage

1 market management systems.

2 And we see that as a potential area. There is a
3 lot of room for improvement that results in a much shorter
4 implementation schedule, a lower risk of implementation and
5 much lower cost of implementation.

6 What helps in this situation is that these
7 systems are not real time EMS SCALA top systems, which
8 immediately points to the advantage that you don't have a
9 large throughput and high volume of data like you have on
10 typical front end for EMS data systems.

11 Once you have that fact in mind, immediately you
12 get the good candidates for kind of integration techniques
13 to use in similar systems, in communications, banking, phone
14 industry, gas industry, which are mature third party open
15 products which definitely reduce costs of implementation and
16 make implementation a kind of modular and flexible for
17 changes in the future.

18 And these are practically the main aspects of the
19 integration techniques that we have to use in systems like
20 this to guarantee that we achieve minimal possible cost in
21 start-up for the systems, in future maintenance and other
22 notational changes.

23 We at Siemens about five or six years ago have
24 started a very expensive overhaul of our product, trying to
25 prepare our product for what's coming for this deregulation

1 of market from traditional EMS customers to GENCO, Transcos,
2 Energy Market Systems, EMSs. So we kind of split our
3 components and make it kind of flexible to assemble together
4 for different needs.

5 Because initially we realized that many of these
6 components the same components are used in these different
7 market segments. That fact and fact that throughput, as I
8 said, and amount of data going through is kind of relatively
9 small compared to traditional large EMS SCALA systems
10 pointed us to use of integration techniques that is heavily
11 used in other industry called enterprise integration bus
12 with XML message payload.

13 There is a significant number of third-party
14 vendors who have very mature product in this area. We early
15 realized that using this approach significantly cut our
16 integration/implementation testing cost and produced a
17 system with great flexibility for changes in the future.

18 Another aspect of our approach is that we are
19 seeing more and more that software development is expensive.
20 Customized systems are very expensive and very risky.

21 In a competitive environment where prices are
22 practically bare bones prices, you as a vendor are in a
23 situation where you enter with a low price a very complex
24 system, a lot of customization which is very difficult to
25 estimate and predict.

1 You typically run into a scenario where you are
2 not happy, business is not healthy, customer is not happy,
3 regulator is not happy. Overall situation is not good for
4 anybody involved in the business.

5 That's why we heavily push and advocate
6 standardization since five, six years ago at EPRI, and we
7 hope today we'll talk more about that. Because we believe
8 that using standardized components--and we have a pretty
9 good idea of how to functionally encapsulate components to
10 minimize interruptions and to have some good
11 functionalization--definitely a wise possibility that has
12 definite impact on the reduction of the cost.

13 Another aspect in what we are promoting is that
14 because of software development expenses we cannot, as we
15 did in the past, develop everything and have every sort of
16 component.

17 We want to be global solution provider but we see
18 other companies at some point in time have a good software
19 components and we'd like to use those components when we
20 provide system solutions.

21 And in order to do that, we have to open our
22 system. We have to have architecture of our floating
23 components from specialized companies which is at a point in
24 time the best in the market can fit in our system with a
25 cost that is reasonable. But that can still fit the

1 functionalities we need but at a reasonable cost.

2 So that's another driving force in taking this
3 approach. I would like to mention other aspects of this
4 large system, and that is maintaining data model for this
5 system. These systems, what we mention here a couple of
6 blocks, we're talking about a large number of functions on
7 which of these blocks, and there is a large amount of data
8 and modeling requirements to support these kind of systems.

9 And then you're working in one environment where
10 one TO doesn't want to be and this RTO wants to be another
11 one so you have to be able to modify those models, expend it
12 in a way that your system doesn't stop, it doesn't cost you
13 a lot to do that.

14 So another really important aspect in our
15 approach is that we firmly believe in centralized data
16 maintenance of the model, a CIM-compliant, EPRI CIM-
17 compliant model. That is something that is very expensive
18 in existing systems. If you talk privately to any of the
19 existing ISOs, RTOs, they will tell you a lot of cost is
20 incurred by just maintaining modeling their systems.

21 Once you see that something finally good is
22 happening for vendors, and that's the fact that technology's
23 finally outrunning consultants so our requirements of
24 consultants are improving all the time are beginning to lag
25 behind technology, so IT technologies communications

1 operating system, the open tools are in very, very good
2 shape today.

3 And once you start using those things, that
4 they're kind of default when you start thinking about what
5 to use to solve some problems, you automatically get to
6 something that is used in all other industries. That is
7 what we call Application Service Provider Model, or leads in
8 the software.

9 We tried that model, or what used to be, or
10 supposed to be a LANS RTO and we were able to deliver that
11 whole system in market trials as the service on the web.
12 All the software was in our data center and software of
13 other companies integrated in the traditional bus and work
14 the frame relay, and all of our customers' side, we used to
15 be a large computer center in a relativelyh small building
16 with a few people working there.

17 As I said, this was automatic result of when you
18 start collecting all these IT tools and see how other
19 industries are addressing software business and we firmly
20 believe that is the future of our business too.

21 That would be in short what I can say unprepared
22 for this topic.

23 MS. SILVERSTEIN: Thank you. Now each of you
24 prepared a five-minute statement on a mystery topic and I am
25 eager to hear what each of you have to say.

1 It has been a real busy month and so we didn't
2 have a chance to prepare as much and be as organized as we
3 would like to be for this, and thank you all for rolling
4 with us today. I'm sure we will all get something out of
5 this, even if we're surprised at what it might be.

6 Let's start with Mr. Britton please, and hear
7 what you've got to say.

8 MR. BRITTON: Thank you. My mystery topic is
9 standards for software.

10 First of all, I'd like to say that Alstom fully
11 supports the idea of SMD, standard market design. We think
12 that there are technical challenges of course, as there are
13 in any large software project and some special challenges,
14 such as the tendency toward larger systems as we move in the
15 direction the FERC is heading. But we don't see any show
16 stoppers here. The thing that we thought was probably going
17 to be the most interesting topic for the day was the
18 opportunity that SMD provides for software standardization.
19 Market standardization kind of leads logically to what can
20 you do in the way of software standardization.

21 And we have some specific recommendations.
22 First of all, we are committed to the principle of open
23 competitive supply and we think these standards and
24 regulations around markets can help foster this goal, and in
25 additional standardization regulation can do things to make

1 systems more effective as well as affect the competitive
2 nature of supply.

3 Appropriate standardization regulation, though,
4 is a theme that I want to hit hard here. Appropriate means
5 you have to look at the cost/benefit case of what you're
6 proposing and prioritize those efforts. Of necessity, we're
7 going to have some groups that need to focus their attention
8 and they need to pick the highest priority fruit first and
9 work on that. And standards are not automatically good.
10 Standards need to be well chosen and well designed.

11 So we have a list of what we think of as high
12 leverage areas for standardization and I'll just summarize
13 those quickly here. The first one is security which has to
14 do with identifying the people that are dealing with the
15 market systems and what their permissions are. And this is
16 standard computer industry stuff that ought to be handled in
17 standard ways and we should pick something that's consistent
18 and do it.

19 The second one is standardizing the way
20 participants interact with the markets. There are lots of
21 examples of good standardization efforts out there that
22 solve problems like this one. The standard market design
23 should make this relatively easy topic to get our arms
24 around and highly beneficial because it'll result in a
25 higher quality understanding of exactly what that interface

1 is.

2 Third item. We should require open software
3 interfaces to encourage vendor competition, and I didn't use
4 the word standard there, I used the word open. And that's
5 because I think the biggest bang for the buck is simply
6 making sure that interfaces are disclosed and that there
7 aren't any legal constraints on the use of those interfaces
8 by other vendors that want to compete in supplying
9 components to the market.

10 It is possible to go further and talk about
11 supported interfaces and standard interfaces but one has to
12 recognize that those take, have a lot more cost and a
13 certain amount of risk in terms of going through the design
14 process to achieve those. In certain situations, it may be
15 justified.

16 The fourth item is another open one. And that's
17 make the power system model data around the industry open.
18 That is make it available, make it so that when we I think
19 Petar alluded in his talk to the importance of the power
20 system model preparation in putting a market system together
21 and indeed in the quality of the market the results. It's a
22 very difficult process and one of the practical problems
23 that hits us in building models and building systems is
24 access to good data. Because access to data is impeded by
25 proprietary contractual constraints between vendors of

1 systems and the owners of those systems.

2 We'd like to see those constraints removed. If
3 we could just get the data and understand the format it was
4 in, it would help us immensely.

5 Our fifth item also deals with modeling. At the
6 moment in the process is building models. They're very
7 difficult. They require quite a few people and they go to
8 quite a few different sources, and the process of modeling
9 is one in which you're looking, you're just trying to find
10 any source for the data, and the quality issues are not
11 dealt with adequately in our view. And I think that it
12 would be very important to stabilize the whole concept of
13 markets and put it on a solid foundation to develop better
14 quality standards for the models on which all of these
15 computations are based. Garbage in, garbage out. You got
16 bad data in, you got bad data out.

17 And we think it's quite feasible to come up with
18 some good ways of assessing model quality.

19 MS. SILVERSTEIN: Let's talk about that for one
20 more second. When you're talking about model quality,
21 you're really talking about the underlying data quality,
22 correct?

23 MR. BRITTON: Accuracy of the model in
24 representing the power system because you can't get good
25 results out unless you have an accurate model of the power

1 system. Essentially, you're going to be solving the wrong
2 system if you, if you --

3 MS. SILVERSTEIN: But is that a function of the
4 fact that you have inaccurate depictions of how for instance
5 different units work, or what the impedance on different
6 lines is, or is it a function of the fact that you have bad
7 data on what a different unit is actually doing in real
8 time.

9 MR. BRITTON: No, no.

10 MS. SILVERSTEIN: What you've got built into the
11 model or the data that you're feeding into the --

12 MR. BRITTON: It's not the real time data that
13 I'm talking about here. It's the underlying model and it
14 goes to all aspects. It's how the system is connected
15 together in reality, what the actual characteristics of
16 units are, the impedances of lines, the modeling of loads.

17 MS. SILVERSTEIN: So to be very clear, what
18 you're talking about is not data quality so much as the
19 quality of the assumptions? Now those assumptions may be
20 built on data that you can't get your mitts on, but --

21 MR. BRITTON: Sure. There's a large quantity of
22 static data, what is sometimes referred to as static data,
23 that's loaded into the system to represent the power system.

24 Yes, sir?

25 MR. HEDERMAN: Let me jump in. If I'm

1 understanding you correctly, you're also talking about the
2 functions and the solutions and it's not simply the data
3 about it, but it's how you're solving as well, that is part
4 of what you think is needed to get to be accurate. Is that
5 correct?

6 MR. BRITTON: It's part of it, but as a for
7 instance, the State Estimator contains, is a function that
8 tries to minimize the difference between measurements and
9 model. And the objective function of a State Estimator is
10 actually a measure of model quality. It's how, if your
11 measurements were perfect, okay. So it would tell you how
12 accurate your representation of the power system is if you
13 tracked that through time.

14 MR. HEDERMAN: Is there a model today of the kind
15 of quality assessment that you're talking about?

16 MR. BRITTON: Not to my knowledge. There are of
17 course lots of State Estimators running, and individual
18 engineers who work on those State Estimators I think
19 probably take more or less care with going back and
20 correcting models and trying to improve that objective
21 function. But I'm not aware of anyone who has ever done a
22 scientific evaluation of what was a good objective, what was
23 a good estimator, what was a good model. And I think it's
24 probably high time we do that.

25 MS. SILVERSTEIN: I'd like to take the MC's

1 liberty of suggesting that we put in a marker for
2 discussing at some future point, after we go down the row,
3 let's come back to the question of what makes a good
4 estimator and what are the vulnerabilities of that and how
5 do you make an estimator model better. And let's wrap up
6 your list of high leverage areas for standardization.

7 MR. BRITTON: Well, that was my last item and my
8 closing statement is simply that we need a standards process
9 of course for dealing with this. We need a neutral forum,
10 which has a proven process. We need to have an interest
11 group that is focusing on these problems and working groups
12 and so on, probably staffed voluntarily by parties who are
13 interested.

1 And once we get a standards process in place, it
2 should also have a lot to do with prioritizing the
3 propositions. And some of the things I've mentioned like
4 just creating open access to applications and to data can be
5 accomplished almost immediately, because they are not
6 technical problems. Or at least I say that optimistically.
7 Thank you.

8 MS. SILVERSTEIN: Thank you very much.
9 Mr. Alsac?

10 MR. ALSAC: Webster's dictionary defines
11 "standard" as something established by authority, by custom,
12 or general consent, as a model or example, and gives things
13 like criterion, yardstick, touchstone, as synonyms. On the
14 other hand, "guideline" is defined as an indication or
15 outline of policy or conduct.

16 Based on the time constraints we are facing in
17 the development of markets, most of which should be
18 operational sometime next year, in the development of these
19 markets, I am more inclined to adopt the guideline
20 definition for the present purposes of SMD.

21 Question: The first question is: What should be
22 standardized? Or what should we have guidelines developed
23 for? To keep innovation, competition, and healthy
24 technological progress, we should direct our attention to
25 standardizing, first, market design, then data requirements

1 and modeling-related issues as mentioned before.

2 Together with mandatory, open-system
3 architectures that will facilitate plug-in market-related
4 software -- this involves standards or guidelines for market
5 definitions, market designs, market data requirements, and
6 data exchanges between market -- different market systems
7 and subsystems, electrical networks and their market models,
8 and open-system architectures.

9 Second question is whether there should be a
10 standard data model. The experience has shown that it is
11 very difficult to come up with detailed data models or data
12 dictionaries, et cetera, that cover all the implementations.

13 Attempts for these in the past, for example, by
14 IEEE, by EPRI, ended with limited success. Again, such
15 standards are useful, as long as they are simple and are
16 used as guidelines. If we go into very detailed
17 descriptions, it will take a very long time, and it will
18 never be complete.

19 The third question I have is the potential for
20 developing datasets to benchmark the needed software.
21 Dataset were developed, and, by default, adopted by IEEE in
22 the early days of electrical network solutions by computers.

23 They were limited in features, but helpful in
24 establishing some benchmarks, mainly for software
25 developers. Similarly, developing datasets to benchmark

1 market software may be helpful for the software developers
2 today, and will definitely instill some user confidence in
3 the software.

4 However, market software is very complex, with
5 many different features and it is not easy to provide
6 benchmarks to cover all the aspects of every application.
7 Again, it is recommended that we should not try to
8 standardize in great detail, but to have guidelines and see
9 how those guidelines direct the development of the standard
10 market design.

11 Furthermore, software benchmarking is an area
12 which we should be very careful to do fairly, considering
13 all the different factors, not only for software, but other
14 things like hardware platforms, compilers, measuring similar
15 models of similar applications, in short, comparing apples
16 with apples. This is usually a very difficult process, much
17 more difficult than it sounds.

18 The final and fourth question I have is the need
19 for user-friendly, transparent interfaces that will help
20 instill confidence in the process. In my view, confidence
21 in software is best instilled by explaining its
22 functionality to the people who are going to use it or be
23 affected by its use.

24 For instance, we need to educate market
25 participants in market-related issues in order instill

1 confidence in the market software. Unfortunately, this is a
2 process that can take a long time.

3 Another way to inspire confidence is to provide
4 stand-alone software, not integrated into the ISO systems,
5 but stand-alone software, which market participants can use
6 independently for learning and simulating the ISO RTO
7 software.

8 For this purpose, we need ISOs and RTOs to
9 publish their data correctly, completely, and consistently,
10 as frequently as possible. Standard market design
11 initiatives should definitely cover this in its scope.

12 Thank you.

13 MS. SILVERSTEIN: Thank you. Dr. Irisarri?

14 DR. IRISARRI: Okay, thank you. Most of the
15 issues, of course, have been addressed already, but I would
16 like to reiterate a couple. Personal experience,
17 interfacing with RTOs to simply look at the data is being
18 published today, indicates that there is no standardization
19 whatsoever in market participant access to the RTOs. If you
20 go to the websites of the New York ISO, New England ISO,
21 PJM, you are going to find a completely dissimilar
22 presentation of the same information.

23 The access mechanisms to that information are
24 completely different in each of those three cases. Just to
25 give you examples, if you want to download a piece of

1 information from New York ISO, you have to use a totally
2 different mechanism than if you want to download the same
3 information from PJM or others.

4 That kind of interface, that kind of a
5 standardization is actually the easiest standardization. It
6 is a lot easier to standardize those components than to
7 standardize a data or to standardize a programs or to
8 standardize interfaces, as a matter of fact, between those
9 programs.

10 So, we suggest that that would be one of the
11 important concerns of the FERC and its staff, to look into
12 interfaces for the market participants and market users that
13 facilitate the provision of data to the systems, as well as
14 the downloading.

15 Data availability, of course, has been mentioned
16 more than once. That's a very important concern. All of
17 the not only market participants but software vendors are
18 very interested in having access to data that can be
19 accessed.

20 Of course, there is always going to be a certain
21 amount of private, secured data that belongs to the
22 different participants. That is harder to provide in the
23 real-time. Maybe it can be provided later, but data
24 availability is particularly -- data to do the calculations
25 or to design the programs to do the calculations necessary

1 to support these systems should be a main concern of the
2 Commission.

3 The issue of system size: We, as providers of
4 software, are being imposed very serious requirements as far
5 as developing applications to support system sizes that may
6 be exceeding any of the system sizes used today.

7 Of course, efficiency of markets requires
8 economies of scale and integration, but at the same time,
9 that is going to pose significant problems and solutions.
10 So, there is an need to decide how big is big? A system of
11 the combined size of Southwest Power Pool, Midwest ISO and
12 PJM is a very, very large system by any standard, and any
13 kind of solution, including nuts and bolts, and so on, will
14 be very highly challenged for a system of that size.

15 On the other hand, if you have a set of RTOs
16 operating independently, you have another problem, which is
17 the intercoordination of those entities and the various
18 issues that come out of that process, such as a loop flow,
19 different pricing computer for the same location, by
20 different entities and so on.

21 Therefore, a coordination to deal with the seams
22 problems and to deal with system reliability and system
23 security is still a big concern and should be there as part
24 of the system in the aspect of any design.

25 Finally, another issue we've been wrestling with

1 for a long time and was mentioned by Jay and Ongun and
2 probably everybody will deal with this one as well, is the
3 modeling concerns. How accurate is accurate, and what is
4 accuracy versus precision? Do we need the precision
5 necessary by solving very complex, what is called AC
6 solutions, or is the accuracy provided by the linear models
7 or DC sufficient?

8 Our experience in operating -- designing,
9 implementing, and operating the IDC, which is a purely
10 linear, so-called DC model, has indicated that it is
11 accurate for the intended purpose.

12 Now, that is a loaded sentence, intended on
13 purpose, and we have to see what is the intended purpose of
14 each and every one of the applications that are going to be
15 implemented as part of the standard market design, and,
16 based on that, decide what kind of a model is needed? Do we
17 really need an AC solution? Do we have to model every
18 single phase shifter in the system to a great level of
19 accuracy, DC models, et cetera?

20 We have wrestled with these ones, these issues
21 for a few years now, and have developed quite a good
22 understanding of the issues, and it always poses a big
23 challenge.

24 Finally, the last point that is of great
25 significance, given the events of the last few years, is

1 system security. And there is access to the system in a
2 secure, authenticated, manner, and the means to do so, based
3 on the available standards such as SSLX.509 and efforts that
4 are being conducted by NERC and other organizations.

5 So, I just bring those points for additional
6 discussion, as we move on. Thank you.

7 MS. SILVERSTEIN: Thank you. Mr. Finney?

8 MR. FINNEY: Thanks. I'll be brief, because I
9 echo many of the comments we've heard already. As the
10 standard market design discussion continues, including this
11 morning, a number of questions have been raised, including
12 the technological capability of supporting very large RTOs
13 fashioned after the SMD.

14 BAAsed on our recent testing and deployment
15 experiences, ABB is confident that today's technology is up
16 to the task for both market infrastructure and scheduling
17 applications.

18 Three commonly agreed objectives of large markets
19 based on the standard market design are: Low- cost,
20 flexibility, and high performance. All of these objectives
21 point to the need for open IT systems that allow RTOs to
22 combine best-in-class applications with a scaleable market
23 infrastructure.

24 At ABB, we've achieved that with our new SABEL
25 market operations system. For example, SABEL has separated

1 market applications from the underlying infrastructure, and
2 from reliance on any one vendor's EMS SKATA system,
3 including our own.

4 Our current SABEL deployment at the Korea Power
5 Exchange combines our market operations system with an
6 Alstom EMS SKATA system, and supporting applications from
7 multiple vendors. The rapid progress that we've made on
8 this project and on the product line indicates to us, a
9 replicable model for market implementation here in the
10 States.

11 ABB asserts that open systems will only be
12 realized if both markets and vendors maintain the strict
13 adherence to rapid development and adoption of standards,
14 which, as we can see, a consensus is forming here today
15 already.

16 The common information model, you know, CIM, has
17 already proven its value in the exchange of static network
18 data. CIM, however, needs to be extended to encompass all
19 the information relevant to standard market operation.

20 In addition, real-time data exchange standards
21 like the one that is supported by both ABB and Alstom,
22 should be promoted by the larger community of users and
23 vendors.

24 ABB encourages the FERC to take a firm stance
25 requiring standards development and adoption. Without such

1 efforts, the true appearance of modular components will be
2 delayed.

3 We welcome and appreciate the FERC's recent
4 inquiries into the ability of today's scheduling
5 applications, including State Estimators, to handle the
6 challenges presented by large markets, based on the standard
7 market design.

8 I'm happy to report that recent tests completed
9 at the New York ISO confirm that day-ahead scheduling for
10 the combined Northeast markets, using our own latest
11 security-constrained unit commitment program, were very
12 successful.

13 For State Estimators, I mentioned earlier, the
14 challenges that standard techniques common to the EMS
15 industry often lack the robustness to converge reliably for
16 market operation, but our recent experience at the Ontario
17 IMO leads us to believe that these problems are quickly
18 overcome, once there's a market impetus to do so.

19 Finally, as mentioned by several of the others
20 here today, we want to emphasize the importance for
21 accounting of the market participants costs. From our own
22 experience, deploying market communication and information
23 management systems for the participants, we know that the
24 costs that participants incur to interface with multiple
25 markets can be staggering.

1 Now that standard markets are becoming a reality,
2 we need to ensure that vendor and RTO efforts at
3 standardization extend all the way to the end user.

4 We're committed to this effort and look forward
5 to working with the markets, the vendors, and the market
6 participants to cement standards in this area. Thanks.

7 MS. SILVERSTEIN: We understand that you guys
8 won't do this unless you get paid, and we understand that
9 market participants, including ISOs and RTOs, won't do it
10 unless they get paid, so we've got that one handled. Thank
11 you for your concern.

12 But that, of course, is one of the reasons we're
13 committed to standardization, is to try to make those costs
14 lower and more cost-efficient for all of the participants,
15 including, most fundamentally, the customers who end up
16 picking up all of your bills.

17 MR. RISTANOVIC: I would like to start from a
18 short look at the current situation of large ISO-RTO
19 systems. If you take a look at what is there in the field,
20 what this country is in the process of building, they're
21 talking about a large, complex, custom, one-of-a-kind
22 systems.

23 And due to the unique nature of these systems,
24 they all have high startup costs, high maintenance costs,
25 very difficult to change, which all has implication on cost

1 and schedule implementation.

2 And that's pretty normal for systems as young as
3 many market management systems, because we should not forget
4 that the EMS system is almost 40-50 years in operation, and
5 they are quite mature and we know how these operate. And
6 these are kind of young systems.

7 What didn't help for the current system is that
8 it didn't have SMD, so it was a high-cost of market design
9 for all of these systems, which is very expensive.
10 Resources for doing this and the process of trying ideas and
11 errors is very expensive and time-consuming.

12 So, we see that by introducing SMD, that cost
13 component will be eliminated, because people will have very
14 nice, specific, precise framework to avoid that high startup
15 market design and trials and errors.

16 And for that we need a reasonable level of
17 details in SMD to make sure that there is not too many
18 deviations. Of course, always take into account, specifics
19 for individual local areas that have to be taken into
20 account, that they are of no importance for some other
21 areas.

22 So we believe that SMD can greatly improve the
23 situation for existing and new RTOs, ISOs, and will have
24 great impact worldwide.

25 Now once we establish kind of standard framework

1 for energy market management systems, immediately comes
2 another opportunity. Since we have defined large functional
3 blocks, there is additional savings that can be realized.

4 If we start looking deeper in this major box we
5 were talking about today, very quickly we can identify
6 smaller functional blocks, the same smaller functional
7 blocks that is in all of these components. I will just give
8 you one example:

9 You will find network applications as a group of
10 functions in FTRs, in day-ahead market, in real-time market
11 in State Estimator, almost all over the place in all these
12 major blocks. And that immediately gives you an idea of,
13 well, why don't we use the same component in all these major
14 subsystems?

15 It's beneficial to use the same model. It can
16 reduce the cost. And it will guarantee compatibility of the
17 solution of these different timeframes.

18 So we firmly believe that there is a lot of room
19 to standardize smaller functional blocks, which will greatly
20 reduce amount of work and integration effort in the system.

21 Another important aspect is if you look into,
22 let's say day-ahead market, real-time market, in standard
23 market design, we will find security-constrained unit
24 commitments, security-constrained common dispatch. But
25 guess what?

1 If you configured security-constrained commitment
2 with some set of flags, you can switch the same engine to be
3 security-constrained common dispatch. So once we identify
4 these functional blocks, maybe another next step of interest
5 would be to define configurable parameters to use that block
6 in different functional environments.

7 So we see a lot of potential there that I'll
8 address later, how that impacts all integration costs, and
9 how that reduces risk for implementation.

10 Another important aspect, in our opinion, was
11 what was addressed by all of the participants, practically,
12 is standardization of data model and data model exchange.
13 And we highly recommend that SMD adopts EPRI's seam as a
14 foundation for SMD standard model. Of course, we have to
15 identify missing parts of the model that are not in the
16 seam, which are necessary to support operation of a market
17 management system, add those extensions and expand the
18 model.

19 Once we are through this stage, once we have
20 functional blocks that are well defined, well encapsulated,
21 naturally, what will happen, what we see in the EMS systems,
22 is that a complexity of modeling and functionality is
23 encapsulated, and what is going between these blocks is a
24 relatively simple interfaces and low amount of data. That
25 is what we saw in traditional EMS.

1 We also find out that many of these components
2 will be exactly the same components that we used for years
3 in EMS systems. That's why you will frequently hear that
4 these energy market systems are not that new; there are just
5 a few new components like OASIS, e-tagging, FTRs, that more
6 or less everything else was there, just put differently
7 together and used in a different way.

8 So we believe that it is a relatively easy and
9 quick task to identify exchanges of data and scenarios, work
10 flows between these functional blocks, which are at a lower
11 level of detail than these large day-ahead and real-time
12 markets.

13 And that would another suggestion to think about
14 as a possibility for standardization. We fully agree that
15 these systems, especially taking into account, events of
16 almost a year ago, have to be very secure systems. Size
17 doesn't help, getting bigger. It's more vulnerable to
18 problems.

19 So, we see a need for establishing some
20 standardizing in security requirements and security
21 platforms.

22 And last and not least, of all of these
23 functionalities you're talking about, we see different kinds
24 of problems in different aspects of energy market management
25 systems.

1 On the one hand, the real-time systems, we don't
2 see many problems in scaling and sizing. We firmly believe
3 that it would be problem for these large systems to keep
4 State Estimator running continuously. You can bring it up
5 once, but then continuous maintenance of data model is a
6 headache, and we have seen that problem much more since what
7 we're talking about large RTOs.

8 In the day-ahead market, we see another,
9 different problem. We were never big advocates for unit
10 commitment for day-ahead market, and I have to repeat that
11 on every occasion. It doesn't help my company, but
12 obviously we have to live with that. It is going to be an
13 SMD, and Siemens has invested a large effort to develop new
14 security-constrained unit commitment. We have a large
15 nodularization, but we developed mixed-integer programming
16 approach because we were not happy with quality, robustness
17 of our solution.

18 However, unit commitment is a tough program.
19 It's especially the kind that we're talking about these
20 large markets. An interpretation of results of unit
21 commitment is even tougher problem.

22 The only way that we know how to measure quality
23 of a solution is to covert to algorithm nodularization, but
24 that's still not good measure. We may have better
25 nodularization.

1 So we have something that we feel is good, but we
2 don't know how good it is, because there is no reference
3 point. You can easily see if your state system solution is
4 good or not. I mean, you can measure that.

5 People who know how to can do it, but it's very
6 difficult to conclude how good is your security-constrained
7 unit commitment solution.

8 Another problem with security-constrained unit
9 commitment is that with different set of constraints,
10 difficulty of problem changes. If you have single-segment
11 price curves, it's different problem than if you have
12 multiple-segment price curves.

13 If you have up and down, short up and down time
14 constraints, it's different than if you have long up and
15 down time constraints. And these changes are exponential or
16 higher than that.

17 So having all this in mind, we firmly believe
18 that to answer all the concerns about visibility,
19 repeatability of solutions as you will see for day-ahead
20 market, we have to establish a benchmark test of reasonable
21 size. I don't know what is reasonable, I mean, maybe 2-
22 3,000 units is close to be upper level reasonable, and
23 publish that model so it can serve as a benchmark to
24 validate existing software, and at the same time, you can
25 encourage other developers to keep improving, because unit

1 commitment -- like, take ten years ago, our big problem was
2 50 units, and we were targeting that market.

3 What we are talking about is huge, and none of
4 us, I don't believe, had enough time to develop a good one,
5 the one that is as close as some traditional software. So
6 we need these to encourage other developers to keep
7 improving these important functions.

8 So this is more or less a list of things that we
9 see are good to be standardized, and we don't believe that
10 we should standardize any implementation, any specific
11 software platform. And this standardization of user
12 interface is on the border, because it's very difficult to
13 standardize user interface and not to standardize any
14 permutations, so you have to be very careful in
15 standardizing access to market information by market
16 participants.

17 MS. SILVERSTEIN: Ah --

18 MR. RISTANOVIC: I'm running out of time? Okay,
19 I'm just going to quickly -- I mentioned -- I would just
20 make one more point; that once we define these functional
21 block, we have everything ready for -- and standard data, we
22 have everything ready for modular, open-access system.

23 And in the afternoon, we'll share some ideas how
24 this process of standardization can be speed up to be on
25 time for existing and coming RTO systems.

1 MS. SILVERSTEIN: I compliment you all on talking
2 about a single topic and having many, many different and
3 complementary things to say about it. I think we've gotten
4 a good overview of standardization and the needs, as well as
5 a lot of support for commonality.

6 I'd like to start by asking a question about the
7 difference between open architecture and standardization and
8 guidelines, and the degree to which -- how do we do that
9 without stifling innovation in how you make things work and
10 how effective the model is? And yet, how do we assure that
11 anyone of these models can plug into and take the feed from
12 one and be integrated with the others in real-time
13 operations? Is it benchmarking? How do you making open
14 architecture and systems happen is an entirely different
15 question, and that will be my second and followup question.
16 Anyone who wants to tackle it can go first.

17 MR. FINNEY: You raised a good point. How do we
18 encourage rapid performance so that we can deploy these
19 systems quickly, with the assurance, when we start them,
20 that they're going to finish on time, without stifling
21 innovation?

22 And the key here is we need a clear distinction
23 between functional requirements of what the black boxes do
24 and the supporting models of how they do it. I may have
25 misheard, but earlier today, I thought I heard, you know, an

1 attempt to standardize methods and models that we will use
2 inside of approaches, such as State Estimators and real-time
3 schedulers.

4 I strongly encourage against that; rather, if the
5 markets themselves can reach a consensus of an
6 interpretation of the SMD that can clearly state what are
7 the functional requirements of each of the components, and
8 then, of course, the vendors sign off that that is a vendor-
9 neutral approach to the specification, then we can chase our
10 own profit motive to do what we do best, which is to
11 innovate and to chase those specifications.

1 Would that end the benchmark of data sets that
2 represent actual markets in operation today and, you know,
3 includes together markets to represent larger RTOs I think
4 is a good first approach toward establishing the benchmark
5 data sets that we can tell whether that's working or not.
6 Did that help?

7 MS. SILVERSTEIN: So you use the benchmark data
8 to validate that you're putting the same data in and you're
9 getting the same result out regardless of what's inside the
10 box?

11 MR. FINNEY: Yes. It's not quite as that, of
12 course, in practice, but we have to start there first.

13 MR. BRITTON: I'd like to go back to your open
14 versus standardized and try to first of all paint -- what I
15 mean by "open" is a view in the case of a particular
16 application, and I recommend looking at this application-by-
17 application and looking at the boundary between that
18 application and the rest of the system, so that the rest of
19 the world and the application are the only things you're
20 talking about. You're describing what the information is
21 that is transferred to the application and from that
22 application.

23 And "openness" means that that information is
24 there, available to another vendor, so that that vendor
25 could write an alternative version of that component and

1 plug it into the system.

2 It doesn't mean that it's there in a standard
3 form. That component vendor who might want to have a
4 competitive version of that module might in the case of one
5 system vendor have one definition, and in another system
6 vendor, have a second definition.

7 In this marketplace, though, there aren't that
8 many combinations. And in terms of cost effectiveness, you
9 get most of the value of open competitive supply simply by
10 making sure that everybody's interfaces are available for
11 use.

12 Standardization is -- it changes the picture. It
13 adds some value in the fact that you can write only one
14 interface, but it costs quite a bit to achieve. And it also
15 can, in some situations, act as a constraint on the
16 development of better algorithms. And in certain
17 situations, it's probably justifiable to go farther. But I
18 think we should be cautious about going farther and eager to
19 go that first step of openness that achieves a lot very
20 easily.

21 MS. SILVERSTEIN: Mr. Ristanovic?

22 MR. RISTANOVIC: I had a couple of years
23 opportunity to discuss with Jay at forums, and we have a
24 small difference of opinion in this respect. Opening
25 interface is a good first step. But that means that Siemens

1 as a vendor has to have interface for ABB, Nexant, OATI,
2 ALSTOM, all of this. When you have standard interface, we
3 have one interface to all of them. It's a small
4 distinction. And I agree with Jay, we're talking about a
5 small number of components, and that's why I think it's not
6 a big deal to switch from open interface to a standard
7 interface.

8 You raised a very important question about
9 standardizing but not preventing competition. By properly
10 defining functional blocks, you leave a lot of room for
11 competitive improvements of components. Because this
12 interface again, a very small part of the business, that are
13 just making plug and play easier.

14 MS. SILVERSTEIN: I assure you that this agency
15 is all about promoting competition and open access, and we
16 would not want Standard Market Design to promote monopolies
17 or create monopolies and barriers to entry.

18 MR. IRISARRI: I would like to give one example
19 of a standard that is available to everybody and everybody
20 can submit their own solution, their own little mouse trap
21 and be successful if they want to, and that's the Italian
22 standard that was developed by NERC and the NERC committees.

23 That standard defines in complete detail what an
24 electronic tag should contain, how that piece of information
25 should be exchanged between different parties, how should it

1 be manipulated and process. It doesn't say how I as an
2 implementor have to do it, what sort of a database, should I
3 use seams? Should I use some other database definition? It
4 doesn't say anything about that. It's external set of
5 interfaces.

6 Now anybody can write code to support those
7 external interfaces and be successful if they want to, and
8 we have seen in the industry that that is the case. There
9 are many providers of services to do electronic tagging.
10 That's an example. And that is a very complex, very complex
11 system that encompasses the whole of North America and is
12 active 24 hours a day, seven days a week.

13 And it has to be very, very, very reliable,
14 because it provides information to two main market-related
15 operations. One is the exchange of energy. Second, the
16 congestion management of the system.

17 Now how can that be accomplished in this case?
18 It can be accomplished perhaps in a manner along the lines
19 of -- I have to agree with Jay Britton -- you have to
20 publish interfaces so smaller vendors -- and I'd like to put
21 myself into that category -- can come in with an
22 application, say, security constrained dispatch for the real
23 time, and implemented within the larger context of an EMS
24 provider.

25 And if we know what data can be extracted from

1 that system and in what format is the data going to be
2 available to me, the data that is needed to do this
3 calculation, then I can access the data, and if they tell me
4 your answers have to be provided in this format and this is
5 the set of interfaces that you have to use to provide your
6 answers into a system, then we have a first step towards an
7 agreement on how to implement that software.

8 MS. SILVERSTEIN: So what you're saying is, give
9 me the data set and give me the specs for -- the data set to
10 feed into it and the specs for what has to come out of it
11 and tell me what I can and can't do in terms of assumptions
12 inside the box, and I'll build a box that will take the data
13 and give you the result in the output format that we need?

14 MR. IRISARRI: That is the principle in a
15 nutshell. And we have had that kind of experience with some
16 of the vendors here, particularly ALSTOM. We are co-
17 providers of systems at Midwest ISO, and we agreed with them
18 on interfaces, and we can get the data and we can supply the
19 results. And it's possible to do that and thus allow
20 competition and allow the ingenuity of the different
21 providers to come through.

22 MR. O'NEILL: I'd like to change the topic
23 slightly. I know all of you folks have been working very
24 hard at implementation of you intend or what you think SMD
25 is going to be. Could you just tell us what your current

1 capabilities are, what kind of progress you've made in
2 solving large-scale problems, what kind of timeframes you
3 can solve them in? And if you want to, tell us the type of
4 computer you're solving them on, and address the barriers
5 that you see coming with larger systems, larger RTOs, larger
6 markets, which the Commission has essentially championed?

7 MR. FINNEY: Well, I'll start with an easy one.
8 I'm just going to reiterate the point I made in my opening
9 statement. Actually since the survey results that we
10 provided to you about a week ago, we got very reassuring
11 news from the New York ISO which completed its last round of
12 testing to see could they, or what would be the effort
13 required to schedule a much larger market based on that
14 current system.

15 What they did in that case was to obtain the data
16 from the surrounding ISOs in, by the way, CIM XML format,
17 which made a lot of the standardization issue went away
18 right there.

19 Then they deployed our basic algorithm on the
20 fastest hardware they had available. I apologize for not
21 knowing what that is.

22 MR. O'NEILL: The surrounding ISOs being IMO, New
23 York, New England and PJM?

24 MR. FINNEY: Actually this afternoon maybe we can
25 get some correction or some help from New York in the

1 audience, but I believe it was just PJM and ISO New England.
2 There was some bus modeling into Ontario IMO, but the
3 generation bids terminate at the border.

4 And the good news is, the size of the system was
5 about three times the size of the system that they started
6 with, and they report that for their various experiments to
7 solve times for the day ahead unit commitment, the security
8 constrained unit commitment, were about three times as long.
9 So that the SCUC itself, which is where we address, where we
10 really hit the mixed integer problems, where we worry about
11 it, that was able to converge in about 11.5 minutes with the
12 overall scheduling timeframe falling in well within under an
13 hour, excluding, by the way, some statistics I don't have
14 about transfer to and from the commercial side of the
15 system.

16 But the problem scaled approximately linearly. I
17 need to point out that this is one specific problem and of
18 course it's not generally applicable to everything, but at
19 least it's one piece of hard data that we've seen that
20 suggests that continuing doing what we're doing with faster
21 hardware and tweaking to the algorithm as needed are already
22 ready to support this.

23 So if I were you, I would not hesitate -- or
24 rather, I would not attempt to limit the size of the RTOs
25 based on our capabilities, at least in terms of the day

1 ahead schedule.

2 MR. IRISSARI: I would like to tell you about our
3 experience in developing basically systems to support the
4 Standard Market Design. For the past two years, we have
5 been working on the development and implementation of a
6 complete system including database requirements, user
7 interface, and of course the software to support the auction
8 calculations, including options and obligations, and
9 including point-to-point rights and flowgate rights.

10 We have also developed a complete software to do
11 the real time security constrained dispatch, and we have
12 done some work in the day ahead market. We don't have at
13 the moment a completed security constrained unit commitment,
14 but have a developed related dynamic dispatch calculation
15 which is pretty much is close to the unit commitment, but it
16 doesn't have the same level of complexity.

17 And I'd like to mention some of the parameters
18 under which we are working. We used to do all these
19 calculations de facto standard, which is the PSSE MMWG case.
20 Everybody has access to that case nowadays. It's a case, a
21 powerflow case, that's our source of data. That's in lieu
22 of having a real time case you have to start from a
23 powerflow model. That case has a total size right now of
24 about 40,000 buses, electrical buses, some 52,000 branches
25 and 6,300 generators or so. So it's an Eastern

1 Interconnection model, a very complex, large model.

2 On that model, we do calculations such as the
3 security constrained dispatch, and I can tell you that we
4 can solve a security constrained dispatch within a two-
5 minute period calculation from reading the data from the
6 database, processing the data and writing the results, back
7 to the database, less than two minutes. And typically we
8 are considering on the order of 3,000 generators there.

9 The number of constraints, the network
10 constraints, is over 1,000 flowgates. And we use the main
11 flowgates as constraints, and there are 1,200 constraints
12 in the Eastern Interconnection right now that I model as
13 flowgates. Some of those include contingencies. Half of
14 those include contingencies. I have 600 contingencies
15 represented in this problem and we do that in really
16 desktop type hardware, 800 megahertz, about 512 megabytes
17 of memory in two minutes.

18 Similarly, we have an auction solution. The
19 auction solution is a complex problem, as was mentioned
20 earlier. It takes on the order of 10 minutes to solve for a
21 total of 14,000 bids, these are the FTR bids requested by
22 the participants, of which 10,000 are obligations and 4,000
23 are options.

24 We have about 12,000 point-to-point rights
25 represented in this system and about 2,000 flowgate

1 rights.

2 This is a linear programming problem, as was
3 explained earlier, has linear objective function. We are
4 maximizing that, and linear constraint. So it's a very
5 large linear programming problem. We solved it in about ten
6 minutes. That would be one execution of that problem. Of
7 course, that problem, even though it can be solved quickly,
8 is a problem that has to be solved many, many times during
9 the auction process which may last days.

10 So details on certain calculations, for example,
11 the main type of item that is used in representing
12 constraint is what is called generation shift factors or
13 load shift factors. We can compute those for the whole
14 Eastern Interconnection system, that is 6,300 generators and
15 1,200 flowgates in about 25 seconds right now in the same
16 hardware, which is actually a desktop hardware.

17 And I guess that summarizes our current
18 experience with calculations and integration of this
19 software.

20 MR. O'NEILL: Do you see any barriers?

21 MR. IRISARRI: Of course. There is always a
22 barrier when developing software, no matter how big the
23 computer is. Sooner or later -- it's like the closet at
24 home. Sooner or later you fill it in with whatever you
25 have.

1 (Laughter.)

2 MR. O'NEILL: How much space do you have in your
3 closet?

4 (Laughter.)

5 MR. IRISARRI: Okay. I believe that we can solve
6 -- the main barrier in our experience is going to be t he
7 data here, data provision, and that is the State Estimator.
8 Why do I think so? If you consider, I don't know about IMO,
9 but I know about SPP. SPP has perhaps the largest State
10 Estimator right now in North America, and it is 12,000
11 buses. I know that that State Estimator is not running at
12 the frequency required to do the real time calculations of
13 the security constrained dispatch in real time, which is
14 five minutes, as expected.

15 If they get a solution, they probably get it
16 within the hour for 12,000 buses. Now scale that by a
17 factor of 3 or 4, which is going to be the objective of the
18 model at, say Midwest ISO, PJM, SPP combined, the
19 complexities are very large. So I see a barrier right there
20 in the provision of the data.

21 Now without the proper data, we fall into the
22 syndrome of garbage in/garbage out as discussed earlier.
23 Now one possibility -- and this is an experience that we
24 have had -- is instead of trying to solve the whole problem
25 as one solution based on raw measurements, it appears

1 logical and reasonable to integrate solutions provided by
2 the different regions that compose the larger market.

3 For example, PJM is solving its State Estimator
4 right now. It's much smaller than PJM, but it is solving.
5 SPP will probably solve with some effort, and MAIN, which is
6 another significant component of MISO, may solve. MAPP is
7 the other component or TransLink nowadays, they may solve a
8 smaller State Estimator, 6,000 to 7,000 buses.

9 It seems to me reasonable once you have put all
10 this effort in computing each one of those and maintaining
11 and purifying and validating and checking, to integrate
12 those solutions. There are algorithms that can be
13 implemented that can integrate that solution and find then
14 the large solution for the whole of the region to be used in
15 the next steps.

16 MS. SILVERSTEIN: Clearly that is what you have
17 to do as a workaround I guess in order to live with what
18 you've got and what you're able to have, but the drawback to
19 doing that that we would like to surmount someday in the
20 future is that we will always end up with suboptimal
21 results, and we will be perpetuating seams in operation. We
22 will be underestimating what we can transfer from one region
23 to another or perpetuating or creating contingencies that
24 may not be in fact materially important for grid operation.

25 So I guess we have to live with it, but we want

1 you guys to keep building the closet bigger so that someday
2 we can avoid that.

3 MR. IRISARRI: Just to clarify here, I'm saying
4 that this solution that we are after is for the whole
5 system, and it would be equivalent to the solution as if you
6 had computed it for the overall. It's just that the
7 integration process of the solution has to be done properly
8 such that the answer is equivalent as if you had solved it
9 as one, unique large system. Is a hierarchical process of
10 integrating the solutions without compromising on accuracy.

11 MS. SILVERSTEIN: Did anyone else want to tackle
12 Dick's show off your statistics question? Mr. Britton?

13 MR. BRITTON: Show off my statistics, huh? Well,
14 first of all, I want to question the SPP State Estimator
15 information. I don't believe that that's the correct
16 current result down there, but I can't quote the numbers.
17 So I'd have to take that one off line I guess to figure it
18 out, but it is one of our systems.

19 MR. O'NEILL: Is that your State Estimator?

20 MR. BRITTON: Yes. That's one of our systems, so
21 I don't want that to stand uncontested.

22 (Laughter.)

23 MR. BRITTON: We've been running more generally,
24 of course, we've been concerned about the increase in size
25 and we've been running tests. I mean, we've run for

1 instance 25,000 bus State Estimators that are in the 15- to
2 30-second range, and real time dispatch in the 12,000 bus
3 system range at 20-second solution times.

4 We have results that give us confidence in saying
5 we can move forward, we can move upward in size. We're not
6 at the limit. We are pushing our technology, and we are
7 creating some challenges, but they're not -- I mean, so were
8 we all the way this process, and I don't think that we have
9 created something that is an especially high barrier here as
10 long as we recognize that increasing size does create some
11 challenges.

12 I also would like -- I used to do network
13 analysis, but these days I do more system design, and I
14 would like to say here that a lot of the challenge is often
15 not in the particular algorithm but in the overall movement
16 of information through the system. When you're dealing with
17 a 12,000 bus system as compared to a 2,000 bus, it's about
18 six times as hard to get your arms around what's going on in
19 the system when there's a problem.

20 Visibility of the system to users and to
21 debuggers of the system becomes a problem. Going back to
22 the data issues, if you make an RTO with a very large
23 footprint, what you've done is increased the number of
24 sources of data that are being combined at the modeling
25 level, power system descriptions, and you've increased the

1 number of sources that you're combining in the SKATA sense,
2 so you get more time skew in the SKATA information.

3 And there are a lot of fairly mundane kinds of
4 problems at low levels that get bigger and bigger as you go
5 on. And we should be paying as much attention in those
6 areas as in algorithmic.

7 MR. ALSAC: Again, we have done some of our
8 experiments. We had created a Northeast ISO size system
9 comprising New York, New England, PJM, run those tests, and
10 we have of course done -- our State Estimator is running in
11 Maine, which is one of the bigger State Estimators, and we
12 extended these data. We extrapolated existing results to
13 much bigger systems, et cetera.

14 And really, for the type of software we have, we
15 have all the market-related software except security
16 constrained unit commitment, we think algorithms and
17 software technology can handle the existing ISO, RTO type of
18 applications, and they are scalable to provide acceptable
19 solution times for bigger systems.

20 Again, as everyone indicated, there are limits to
21 this, but also the performance increases with number of
22 faster computers. Like everyone, we did all these tests
23 using desktop computers which are much different than some
24 of these multi-CPU servers and other things which are
25 faster. And with number of processors going up of course,

1 there is a possibility of getting some kind of increased
2 performance.

1 The main problems we see, like everyone else, is
2 based on our past experience with EMSs of smaller size and
3 now EMS with RTO-ISO size, is really poor measurement
4 quality, poor redundancy, unsatisfactory data quality, poor
5 data exchanges, which are format and content incompatible.

6 That results in either not working state
7 estimators, or poorly solved grid models, which is, again,
8 provided by State Estimator to the rest of the other market
9 applications. I mean, once the State Estimator model is
10 bad, everything is based on it, and then everything follows
11 that, and that will be bad, so this is, we see, really, a
12 major problem that, as the systems grow, I think attention
13 to data problems do not grow proportionately. There are
14 committees drawing data together, expecting ISOs to make it
15 work, rather than very detailed analysis making the gaps
16 between existing areas and multi-area, multi-region ISOs are
17 lots of gaps of data that's not provided.

18 There are still ISOs where State Estimator is not
19 working, and will take time to work, and like they are -- I
20 was in some -- I was hearing in some meetings that
21 California ISO State Estimator will work by the end of the
22 year, and it has been the same story over the last couple of
23 years. And it is, again, not due to algorithms; it is not
24 due to software technology; it is the data, missing data,
25 and bad data that is provided to these algorithms.

1 MS. SILVERSTEIN: Perhaps we could take the data
2 quality issue, as well as the benchmark data issue and put
3 them aside and bring them back in our closing session of the
4 afternoon, where we're actually going to be talking about
5 what do we do next and what are the priorities, and who
6 needs to do them?

7 MR. ALSAC: I think that's an excellent idea.

8 MS. SILVERSTEIN: Thank you. Mr. Ristanovic.

9 MR. RISTANOVIC: Well, in the answer to the
10 question about the expression about anticipation of SMD, we
11 didn't spend much time on SED real-time State Estimator.
12 Everything is fine there. We tried up to 30,000 buses, a
13 good number, sequence, one-minute cycling, five-minute real-
14 time market, so we don't expect performance problems there.

15 We fully agree that the quality of the data is
16 the key issue there. Again, not to bring it up first time,
17 but to keep it running. Because, the first time, while we
18 are their vendors, we can clean data, find what the problem
19 is. Once the utility take over -- not all of them, but some
20 of them are pretty good about that. I would single out PJM
21 where -- running. They have not that problem, but they
22 dedicated a large staff to maintain the State Estimator,
23 especially when they started expanding the system.

24 Where we focus our energy with day-ahead market
25 unit commitment, and we are -- we spend a lot of work there

1 in anticipating co-optimization of energy services,
2 interruptible load bids, those were major efforts that we
3 put in place, and parallelization of mixed-integer
4 programming solutions.

5 So, we are pretty pleased with what we see, how
6 it scales for our PCUs, because it's part of the
7 methodology, and that's our main effort, to improve
8 robustness and quality of solution of day-ahead unit
9 commitment; in other words, the same question has to give
10 you the same answer.

11 MR. LUONG: I think so far we're talking about
12 the size of State Estimator and everything, and the size of
13 the system. And I think the next thing I would like talk
14 about is the battery of the RTOs. I mean, I've been to
15 school and I worked in State Estimator, and I learned State
16 Estimator and I know that running the State Estimator --
17 solving the State Estimator in the lab is easy, but running
18 the State Estimator every day, 24 hours a day, is much
19 harder.

20 So, now, you don't have -- you have State
21 Estimator solution and you may have things like that. Now
22 we go to the next step, going to the security-constrained
23 dispatch and security-economic-constrained dispatch.

24 What happen if your battery is in a situation
25 that you cannot get a solution? Because of some of the

1 units that you need to be in that is out of your controlling
2 area, and because of the configuration of the RTO right now,
3 you may run into the situation like that.

4 The unit that you want to move would be outside
5 of our authority, and this one will give you the situation
6 just like Alison just mentioned. You become the suboptimal,
7 you know, the electrical island. So how do you solve that
8 problem? You see that the battery of the RTO would be a
9 problem.

10 MS. SILVERSTEIN: The only good is that we'll be
11 perpetuating commercial seams and obstacles, except for
12 technology insufficiency reasons instead of official, formal
13 market player barriers and opposition.

14 DR. IRISARRI: Always, that's a hard question to
15 answer. But perhaps just reflect the expedience -- today,
16 as we know, because of all the reasons that have been
17 brought up, State Estimator fails here and there. Even
18 power flow fails.

19 As we increase the size of the system and as the
20 data requirements become more stringent and the data
21 qualities become poorer, as the integration of all of these
22 systems tend to fail, then we -- the State Estimator itself
23 may not be able to solve or may not have a solution for the
24 whole area of interest.

25 In that case, what is necessary to do is the same

1 things that are done today: Is to extend the area of
2 interest by pseudo-measurements or other information that is
3 previously obtained through the history of running the
4 system, and replace the lack of real-time data. And that is
5 done today for the external systems by statistically-
6 equivalent and reasonable information.

7 And then you would have a solution where you can
8 incorporate the missing piece, say, a generator or a load
9 that you have to provide. You cannot just throw up your
10 arms and say I cannot continue. You have to obtain a
11 reasonable solution, given the approximation.

12 Now, that touches on what is done today, say, for
13 a real-time system such as the IDC, which is not using real-
14 time data; it's actually using a power flow mode that is
15 kept as close as possible to real time with information
16 provided continuously, such as altitude formation, changes
17 in equipment, transmission equipment, and as well as
18 generation equipment and so on. We kept it up to date as
19 close as possible to reality.

20 The same thing and the same sort of process has
21 to be used to deal with real-time problems, and it's being
22 done to a great extent now. That's my take on it.

23 MS. SILVERSTEIN: So, operational -- I'm still
24 stuck back at the surprise I felt when you all said, oh,
25 we're only running the State Estimator once a day, because

1 it's our practical experience that, you know, power plants
2 and lines go down pretty much when they want to, and that
3 the condition of the grid at the point of time when you've
4 got all your EMS in, and you're saying this is what it looks
5 like now. I'm sort of stumped as to how you then -- I mean,
6 you build your unit commitment, and you've got a pretty good
7 idea of what's going to be happening, based on your day-
8 ahead, but then life happens.

9 And is the State Estimator just the building
10 block, and then you're doing something completely different,
11 based on the results of the real-time market? So are you
12 just setting that as the foundation for the day-ahead and
13 doing real-time adjustments?

14 DR. IRISARRI: Just one clarification: First of
15 all, the State Estimator, I didn't say once a day; I said
16 within the hour, once an hour or, say, every 30 minutes.

17 The objective is to run the State Estimator as
18 quickly as possible. If you can run it every second or
19 every two seconds, that would be great. Now, today, in
20 spite of not being able to solve the State Estimator every
21 five minutes, you still have real-time information
22 available.

23 Every system has a SKATA data that is being
24 collected at frequencies of a second -- some of the data.
25 Some of the data maybe 30 seconds or a minute. And you can

1 actually operate the systems, based on those data, and make
2 some decisions.

3 But then you run the very high risk of making
4 decisions on wrong information. The whole purpose of the
5 State Estimator is to clean up that dataset and provide,
6 within the bounds of accuracy, a good solution that has
7 eliminated bad data and so on. That's the principle of it.

8 8

9 For very large systems, as envisioned here, and
10 for the requirements, the economic requirements of a market
11 in which you have to continuously compute price signals,
12 LMPs, as quickly as possible, five minutes is the goal, and
13 that's what's being done today, say, at PJM or New York ISO,
14 and so on and so forth.

15 Now, for a system such as MISO, of the size of
16 40,000 buses or so, encompassing, perhaps, parts of SPP and
17 PJM, the expectation that you can run the State Estimator at
18 that frequency, five minutes, at least, so you can run this
19 critical dispatch at the same frequency, is a challenge.

20 I'm not saying that it's impossible, but it is a
21 challenge, and putting it altogether with all the data
22 requirements and all the calculations that go in and all the
23 data cleanup that goes along, and the interfaces, is where
24 the challenge is, indeed.

25 And even the algorithm itself, solving a very

1 large problem, is going to be a complicated process, and
2 then if you fail, if for some reason it doesn't work -- to
3 answer once again, Pam -- you still have to have a way of
4 completing your solution, rather than saying I cannot
5 continue.

6 MR. RISTANOVIC: Well, it's not a question, can
7 it solve it in the required time; it has to solve, because
8 basic assumption of SMD is LMP calculations. And for
9 accurate LMP calculation, you have to have State Estimator
10 solution.

11 So if you go higher and in larger models, State
12 Estimator cannot solve every five minutes, and then it has
13 to go every 15 minutes, and then pricing has to go every 15
14 minutes.

15 In the case that you're running every five
16 minutes and in some cycle you don't solve it, you can use
17 previous cycles, because you can see assumption is that the
18 conditions are very close or every five minutes, because you
19 don't have anything better in the system.

20 But you have to have those measures built in the
21 software to take care of unusual situations. But State
22 Estimator, if you make it more frequently running, pricing
23 will be more accurate.

24 MS. SILVERSTEIN: Have you all or the ISOs done
25 any calibration or validation to determine how often, when

1 an unusual situation occurs, the folks who are actually
2 doing the ISO dispatch and control, dispatch the solution
3 that the computer tells you to, or they fall back on their
4 seat-of-the-pants, gut-level understanding of how the system
5 works, based on 15 years of experience? Mark, did you have
6 a question?

7 MR. ROSENBERG: Yes. We've talked this morning
8 about what you're doing and how you're doing it. I'd like
9 to turn it around a little bit and ask the question, what
10 can we do, either through SMD or some other way, to make
11 your job easier?

12 MR. FINNEY: Alison, cut me off if I'm stealing
13 thunder from this afternoon, but one of the things,
14 basically, don't get too nitty-gritty into the technical
15 details. That's fine, but use your hammer to encourage the
16 openness of the systems, to make certain that standards
17 bodies are in place and that a process is in place, and that
18 the process is not one which is just agreed to by the
19 vendors themselves, but, more importantly, between the
20 emerging RTOs, not just within one RTO, but between them.

21 How we do that, is what we're going to try to
22 figure out this afternoon.

23 MR. OVERHOLT: Back to State Estimators, a
24 comment was made that what we would like to do is minimize
25 the difference between what the model says and what the

1 major data is. What we're working with is, of course,
2 synchronized phase measurement data, and if you had that
3 type of synchronized data on voltages and phase angles,
4 would that be a -- I would think that would be a step toward
5 not a State Estimator, but a state determinator.

6 MR. BRITTON: I mean, there are a couple of
7 different things that one could look at as improvements to
8 the way State Estimators currently work. I think all the
9 answers that have been given here so far deal with the State
10 Estimator algorithm as we currently use it, where it doesn't
11 take advantage of phase-angle measurements.

12 But we've had some discussions about wouldn't it
13 be nice if, and certainly the State Estimator needs to be
14 able to take advantage of any information that's available
15 on that. And that information could be potentially very
16 valuable.

17 There are a couple of other things about the
18 State Estimator that haven't been mentioned also. The size
19 of RTO footprints probably is going to increase the number,
20 the frequency of topology changes, and the usual practice
21 with State Estimators when a topology change occurs in the
22 system is to wait a little, because you don't want to catch
23 system dynamics.

24 The State Estimator is a steady-state model of
25 the system; it's not a model that takes into account,

1 swings. So, you know, the question is, when you're feeding
2 more rapid topology changes into the system, is it going to
3 become a problem with the current logic that just says,
4 wait, do you need some way of doing partial State Estimators
5 or using the data that you've got where you can be confident
6 about it to improve it?

7 You know, there may be some work there that could
8 be very valuable.

9 MR. O'NEILL: Just a clarification. Do you
10 consider a change in the phase-angle regulator a topology
11 change?

12 MR. BRITTON: A change in -- on a phase-shifter,
13 you mean?

14 MR. O'NEILL: Yes.

15 MR. BRITTON: I don't believe so. Actually, I'd
16 have to check.

17 MR. ALSAC: We use both transformer taps and
18 phase-angle regulators as state. So we estimate them, if
19 there's enough measurements, so we consider that state, not
20 as topologic.

21 MS. SILVERSTEIN: Phil, did you have any followup
22 on that?

23 MR. LUONG: I had a question. We mentioned about
24 information to the market participants, you know, thing like
25 that. You have any desire for the user interface for the

1 market monitoring to access the necessary data to monitor
2 the market?

3 I got some feedback from normally the MMU and
4 they feel that they are the second-class citizens in the EMS
5 system in the operation. Do you have any software to design
6 anything like that to help them out?

7 MR. RISTANOVIC: Well, it goes along with the
8 question from Marvin about what we think about what you are
9 doing. We don't see balanced focus in level of details in
10 different aspects. And market monitoring is one of those
11 that is not addressed in very much detail, together with
12 volatile markets.

13 So we need more detailed definition of what is
14 going to be market monitoring. And another aspect that is,
15 I think, not addressed well -- I hope it's not a lost cause
16 -- is voluntary market, long-term voluntary deals, which are
17 very important for stability of prices. I don't believe
18 that the ICAP market and the price-sensitive bidding will
19 mitigate, completely, opportunistic bidding.

20 So those two areas, broader market and market
21 monitoring, are not as detailed explained in SMD, so far as
22 what they see as day-ahead market or real-time market State
23 Estimator.

24 MS. SILVERSTEIN: As many of you are aware, the
25 Commission's goal is to release the standard market design

1 proposed rule in two weeks, which means we'll be fairly busy
2 for the next two weeks, and I want to go back to an issue
3 that you mentioned a few minutes ago, Mr. Finney.

4 You said, well, *bridge tapes 9 and 10* the
5 symbols, but don't make them too detailed. But the nature
6 of my question is this: When we say, here, we need LMP, we
7 need this, we need that, I need you talk more about what the
8 level of detail that you need is or isn't, from us.

9 And the second thing I'd like the five of you to
10 address is when we give you these rules in whatever the
11 appropriate level -- in whatever level of detail we can get
12 to in the coming two weeks, and refined by the end of this
13 year for the final rule, how -- there is programming and
14 model design is as much of an art, in fact, perhaps more
15 than it is a science, in my experience.

16 And to what degree can we be assured that when we
17 give you this rule, the result that comes out from a common
18 set of data from Alstom's interpretation of what LMP is, as
19 differs from ABB's, even if you all are working from the
20 same map, how do we make sure that you end up in the same
21 place, and that you don't do interpretations in your design
22 that whether deliberately or non-deliberately, cause
23 different results to actual market operations from the
24 assumptions that you have built into your models?

25 MR. FINNEY: I'll use your specific example about

1 LMP. In two weeks, you don't have time to thoroughly vet
2 everything -- if I view the working paper as a starting
3 point -- to put in all the math that's required.

4 In two weeks, what I would seek to do, first of
5 all, is --

6 MS. SILVERSTEIN: You need to know that I have a
7 stack of 600 pages at home.

8 MR. FINNEY: Oh, my god. Well, I'll save some
9 room on my reading shelf. So, if you can remove the
10 ambiguities as much as possible, so when we're talking about
11 LMP, if you say specifically, we want prices calculated
12 nodally, and we would like for the availability of breakdown
13 of price to reflect the components that pertain to energy
14 and to each of the transmission constraints, et cetera.

15 If you have a view in this area, be very
16 specific. Nevertheless, as you said, multiple
17 interpretations will result, not just among the vendors,
18 but, of course, among the people who will take delivery of
19 the systems.

20 So, in two weeks, be as specific as you can;
21 remove ambiguities, and then look to establish a process for
22 clarifying issues to be addressed and work on that as fast
23 as possible.

24 MS. SILVERSTEIN: When we implement and publish
25 the final rule, that with, I hope, with feedback from many

1 of you in this room in response to the proposed rule, says
2 this is what the level of detail is and this is how it's
3 supposed to work, nonetheless, I expect that when you guys
4 get the draft rule, you'll be going back and talking to
5 your modelers and showing them and saying, look, this is
6 what LMP might look; start working on it.

7 And the dilemma that I envision is when the RTOs,
8 who are essentially our agents in the field to make markets
9 work, go software shopping, if they start with their common
10 dataset, they will be essentially auditioning all five of
11 you. You'll respond to the RFP, and can they actually --
12 what if they run it and they say, okay, well, for the same
13 dataset for the same market conditions and players, we've
14 got -- all of it is LMP, very clearly, but we're dispatching
15 Plant A for one hour longer, and we're committing them --
16 there's a different commitment sequence; there's different
17 real-time run sequences. There's all kinds of stuff that
18 maybe doesn't do great violence to market operations as a
19 whole.

20 It's still a competitive market; it's still
21 security-constrained dispatch, et cetera, et cetera, but
22 different people are running different stuff at different
23 times, and that affects where the gas goes and where the
24 electricity goes, and where the money goes.

25 How do we -- assuming that it's not really an

1 equity issue, as long -- except for the people who aren't
2 getting it, nonetheless, there's some kind of diversity of
3 result. Is that a bad thing? How do we tell how much
4 difference between your results is a bad thing?

5 MR. RISTANOVIC: Well, if you think about how PJM
6 does it today, they run LMPs and they audit results for
7 different software. So it has to be the same, because they
8 are not the same, one of these two is wrong.

9 So result should be the same data, I mean, close
10 enough, the same -- results with the same data, assuming
11 that they are either bad or good, have to be very close, and
12 the software has to be audited.

13 So, from that at point of view, it cannot be
14 compromised, because the party that is losing because of
15 inconsistency has authority to complain about that.

16 The other aspect about dispatching is different
17 problem. If you have two units which have the same marginal
18 price and they are marginal units, and you unload one of
19 them partially, and fully the other one, that's another
20 problem that is problem of software that has also to be
21 fixed. That also cannot sustain market auditing.

22 MR. ALSAC: I think even on very simple
23 applications like a simple power flow solution, you will
24 never get the same results by different vendors. So this
25 market software is very complicated, and trying to compare

1 like the idea that same like an RTO, ISO going to market
2 with the system and comparing, they will never get the same
3 results.

4 So, I think unless you go into extreme details,
5 which is almost software design, then it is much better to
6 keep your recommendations at higher level, and make the
7 definitions -- I think the market definition, rather than
8 data or software implementation of it, because it is really,
9 in my view, very difficult software. For instance, our
10 software is used to audit something in PJM, but they are
11 never giving the same results.

12 And it is like almost the boundaries. You can
13 define the boundaries, maybe. It is even a different
14 approach that the software may not give more than this much,
15 but even like the approximations, the methodology, what I am
16 worried is, you can define certain things, but then you will
17 cover the basic lowest common denominator.

18 And there will be no like room. If you define,
19 for instance, very strictly, data interchanges, then over
20 the next 20 years, it will be very difficult to change those
21 interchanges, whereas maybe adding more to those or changing
22 that thing, you can do much more things, either faster,
23 better, or more innovation. So you have to be tremendously
24 careful in doing some of these things, otherwise, we will
25 all end up with a standard, but a standard may be market

1 design, but a very substandard implementation.

2 MS. SILVERSTEIN: But you now touch on a
3 different issue that I would like to talk about more this
4 afternoon, which is how do we assure that standardization
5 does not inhibit evolution and innovation in both the market
6 design and in the underlying software that enables it to
7 work?

8 But I want to make sure that I understand your
9 recommendation or conclusion on the particular topic of --
10 it sounds like what you're saying is different software will
11 produce different results, accept it, and instead work with
12 users to identify some level or parameter or acceptable
13 slack within which we can say this is close enough; there
14 are not gross inequities or great misinterpretations.

15 MR. ALSAC: This is, for instance, how, currently
16 PJM is working with it. Rather than trying to get identical
17 results, which seems to be, whatever you do, impossible,
18 like the data models, representation of transmission lines,
19 everything is in that detail, could be different. And they
20 affect the final solution.

21 So I think it is better to define the parameters
22 and also to define the market rules that very clearly
23 explains what is required, so that everyone can aim for
24 that. But our experience shows that different software
25 giving identical results, unless it is on a very simple,

1 like, as have been done so far to test systems. Everyone's
2 results are giving yes, you will get the same results, but
3 on an ISO size, 30,000, 40,000-bus systems with all these
4 complications, there is no way to get identical results.

5 MR. O'NEILL: We couldn't even get the three-bus
6 systems to work.

7 MS. SILVERSTEIN: Mr. Britton?

8 MR. BRITTON: I wanted to echo the comments
9 there. I think he's exactly right, that these are way too
10 complicated to get exact matches.

11 And I think you'd spend an awful lot of energy
12 trying to make these -- the specifications, and they wind up
13 causing more problems than they would solve.

14 What might work would be to try to find a way to
15 look for large excursions, and try to understand them, and
16 begin, over time, to get some better benchmarking of quality
17 of results. But, you know, I think that's something that
18 we'd have to set as a long-term goal, rather than something
19 that is achievable in the near term.

20 MR. O'NEILL: But given this sort of
21 indefiniteness to the process, I would assume that it makes
22 the independence of the market operator very important.

23 MS. SILVERSTEIN: We probably also need to make
24 sure that generators and utilities aren't using their spare
25 cash to buy software vendors. Affiliate rules take on a

1 whole new meaning.

2 Let me close the morning with another little
3 softball question for you. What is the level of precision
4 that we need these models to produce? You mentioned earlier
5 when do you need AC and when do you need DC?

6 And the extension of that is, how good do these
7 have to be, how detailed do the results have to be, and that
8 also, of course, has implications for the data in, although
9 we don't have to do the data issue now. Mr. Britton?

10 MR. BRITTON: I'd like to -- there's lots of ways
11 we can go in discussing that question, but I'd like to start
12 it at the State Estimator, because before you can get any of
13 the other solutions, I think you need to just look at how
14 well can you match real-time?

15 And the State Estimator is the application that
16 encapsulates that particular problem. It's a direct test. If
17 you assume that you have accurate measurements, which you
18 don't at any one time, but you, over the longer haul of
19 things, you pretty much have accurate measurements, if you
20 have accurate measurements, the State Estimator differences
21 between measured and estimated are reflecting modeling
22 errors.

23 And I don't have a quantity. I think what I said
24 in my opening remarks is, I'm not aware of any work that's
25 really been done in the industry about saying how good is a

1 reasonable estimator? But I think that's something that is
2 a serious sort of item to pursue. It's something that's
3 been overlooked.

4 We should have been at this long ago, the
5 question of how good an estimator should be able to get.
6 And I think it's a relatively answerable question, I think,
7 if we got together and compared real results from estimators
8 that are running, we could get an idea.

9 I bet we'd find, first of all, variability in the
10 quality, because of the variability in the modeling
11 underneath. And all we'd have to do is to take a look at
12 which ones are running better, and we'd get an idea of what
13 the yardstick ought to be.

14 MR. ALSAC: I think, again, maybe closer to the
15 real time, to the operation, it is better to get more
16 accurate, but as you move away from, and especially as you
17 move into financial systems, it might be understood. I
18 mean, we could decide to exaggerate it to the most we can
19 say, toss the coin, and if everyone agrees that this is how
20 we are going to dispatch, then it is a financial system
21 which everyone agrees and there would be rules.

22 So as we go into the financial systems, although
23 many engineers -- or as engineers, until we disagree,
24 financial systems, we can use DC models.

25 All we need to do is to have market rules that do

1 cover when these approximate models do not provide some of
2 the expected results. For instance, in a FTR, if using the
3 C models we are selling excessive FTRs or underselling the
4 system, there must be some rules to cover. But even if it
5 is an AC, it is possible to sell more or less.

6 So we need these rules anyway, so the more
7 financial, the more I think the question is it is better to
8 initially start with simpler models and maybe in time, move
9 into more accurate models.

10 MS. SILVERSTEIN: But at what point do I decide
11 the model is not producing the right result, and, therefore,
12 I need a rule as to distinguished from the model is not
13 producing the right result, and, therefore, I need a better
14 model?

15 MR. ALSAC: I think, again, it is -- even if you
16 are using very accurate models, there is no guarantee that,
17 for instance, you will not oversell, undersell FTRs. So,
18 you need the rules anyway, independent of the model.

19
20
21
22
23
24
25

1 So in that sense, the question as you move into
2 financial part of it, is not critical but as you go into
3 more system operation, system dispatch, of course, the more
4 accurate you get, the better, because you cannot operate the
5 system at approximate models like DC where the lines are
6 sort of overloaded in the real system.

7 MS. SILVERSTEIN: So it's better to make a
8 mistake and have more imposition on the money than it is on
9 the actual energy?

10 MR. ALSAC: It is not really as simple like I'm
11 not implying that, but it is with the money like there is a
12 system in which everyone agrees within an ISO. At least
13 everyone knows the rules and everyone has time, once these
14 rules are implemented, over a period of time, to analyze and
15 maybe come back and refine the model. But we don't have his
16 in the real time operation of power system. We cannot say,
17 okay, we are going to burn a couple of transmission lines to
18 find out if the accuracy is enough or not. But so we can
19 define the financial models once we start approximate models
20 and work our way into more complex.

21 For instance, in an AA, if we are trying to do AC
22 modeling for FTRs, then the complexity increases an order of
23 magnitude and together with it computation times. So it is
24 even in some cases totally impractical to do certain things
25 very accurately even if we desire that may not be initially

1 feasible.

2 MS. SILVERSTEIN: Mr. Irisarri:

3 MR. IRISARRI: As usual, there are always checks
4 and balances in these systems. Coming back to the FTR
5 location, is a process that you're going to be running say
6 once a year and then you repeat it every month, but there is
7 the associated revenue adequacy issue of the FTR location.
8 If your system is consistently revenue inadequate, meaning
9 that you are paying out more or receiving less than you have
10 a hint that the auction wasn't on the previous month or the
11 previous year is not, something is lacking.

12 ' Now there are many sources. One could be
13 modeling issues, AC versus DC, another simple one could be
14 that you are selling or on there selling your rights because
15 the limits that you have set in your transmission system may
16 not be adequate themselves. And those limits are computed
17 by a totally different entity based on previous experience
18 with the ISO. For example, those limits may be computed by
19 a planning entity which is different than the operations
20 entity. The two at one point will have to come together and
21 the revenue adequacies measure debt just like the objective
22 function of the State Estimator is the check and balance as
23 far as the accuracy of the results of the State Estimators
24 themselves.

25 So at that point, as an engineer, you have to

1 decide where am I going wrong. Is it because I have the
2 wrong model, is it because I have the wrong data that I'm
3 providing to the model and precisely these are the issues
4 that we have been discussing all morning long.

5 MR. FINNEY: You mentioned your agent in the
6 field and those are the ones who are going to answer your
7 question how do we stop, right? Because they beat up on us
8 the vendors to assert exactly two things, and how we get
9 there and what programs we use are not nearly as important
10 as grid reliability, which we've been very good at for a
11 long time, and transparency, which we are getting better at.

12 When their customers and the market monitoring
13 unit can be assured that the prices that are posted are
14 explicable, and repeatable, then we're done, right? When
15 the markets stop complaining, the market participants are
16 happy with the performance in the system, then odds are good
17 that we're finished.

18 MS. SILVERSTEIN: You get points for the best
19 answer in front of a Commissioner. Thank you.

20 MR. FINNEY: Great. Thanks.

21 MS. SILVERSTEIN: Commissioner Nora Brownell.

22 MR. RISTANOVIC: Well there are bigger issues in
23 the ocean than data errors, that are producing large errors,
24 so it has to be something built and designed to care of
25 under selling or selling of FTRs.

1 MS. SILVERSTEIN: I'm going to declare victory
2 for the morning. I've learned a lot. I hope some of you
3 have. I hope many of you have as well. And I thank you all
4 for being flexible this morning. It's been very helpful.
5 We are lucky to have a number of exhibitors. The exhibits
6 are downstairs on the first floor. There are stairways at
7 each end of the building, there are elevators. We are on a
8 break until 1:00 o'clock. There is a small restaurant,
9 cafeteria over here, and there's also Union Station which
10 has lots of restaurants but we'd rather you stay around and
11 look at the exhibits and chat amongst yourselves. So thank
12 you so much and we'll see you at 1:00 o'clock.

13 (Whereupon, the conference was recessed for
14 lunch, to reconvene the same day, Thursday, July 18, 2002,
15 at 1:00 p.m. in the same place.)

16
17

23
24
25

1 AFTERNOON SESSION

2 (1:05 p.m.)

3 MS. SILVERSTEIN: If I can ask those of you who
4 have all your papers to sit down and those of you who don't
5 have all your papers to be real quiet about getting them so
6 we can get started please.

7 I am very pleased to be setting up this next
8 panel which is on security issues and security not in the
9 sense of does the grid work, but security is can we keep the
10 grid up, and all of the operations and software and hardware
11 that support it. And our two guests for this afternoon on
12 security are Howard Schmidt, who is the Vice Chairman of the
13 President's Critical Infrastructure Protection Board, and
14 Chuck Noble of the New England ISO on behalf of the NERC
15 Critical Infrastructure Protection Advisory Group.

16 We're going to start with Mr. Schmidt.

17 MR. SCHMIDT: Thank you very much, Alison. And
18 thank you very much it's a privilege to be here today and on
19 behalf of the President's Critical Infrastructure Protection
20 Board and Dick Clark, we relish the opportunity to come and
21 speak to you about this subject that's near and dear to our
22 heart.

23 In about the ten minutes that I have, I want to
24 sort of break this into three specific pieces. The first
25 part I want to do is sort of set up, if you would, what

1 we've been seeing and what we've been thinking about
2 relative to the broad term of cyber security.

3 The second piece I want to touch on is some of
4 the Board priorities, some of the things that on behalf of
5 the President that we're doing, setting up the priorities
6 relative to cyber security.

7 And the last piece, and by far definitely not the
8 least important is the President's National Strategy for
9 Defending Cyberspace, particularly on the heels of the
10 Department of Homeland Security strategy that just came out
11 a couple days ago.

12 So with those remarks, I want to start out by
13 talking about some of the things we've been seeing recently.
14 We've seen a tremendous increase the past year or so, the
15 number of hack attacks on our critical infrastructure, the
16 Nile Service attacks, situations involving fraud, identity
17 theft, theft of intellectual property, economic espionage
18 that affects us greatly. But what we're also seeing, it no
19 longer takes someone with great technical knowledge to be
20 able to accomplish these tasks. We're seeing the tools
21 becoming very much easier to use. I jokingly talked to my
22 86-year-old father that found a hacker tool and said this is
23 kind of neat, what can I do with it. And in all honesty, he
24 could have done something with it.

25 But also it takes what we're seeing as a

1 repackaging of, if you would, of these tools so you don't
2 have a single thing that it's been shooting at, it shoots at
3 mobile things at one time. So if it looks for vulnerability
4 and it doesn't find it over here, it moves to the next one,
5 to the next one to the next one to the next one, till if
6 finally finds a way through the system.

7 We've seen that recently, by the way, last year
8 in instances where we've seen the Code Red and the NIMDA
9 attacks, which resulted in billions of dollars worth of
10 damage. I think one of the other things we've seen we all
11 agree, and once again thankful for the opportunity to be
12 here today, as the owners and operators of the critical
13 infrastructures are the ones that have the ability to make
14 this more robust.

15 It's not a Department of Defense issue. They
16 can't go out there and do a lot of the things they can do in
17 a traditional sense, even though they do a great job in
18 securing their systems, but it's going to take the
19 collective efforts of all of us.

20 I mentioned the national strategy, and I'll go
21 into detail in a moment, but the national strategy, and I
22 want to make sure we're specific on this, it is indeed a
23 national strategy, not a federal strategy, is to be
24 successful, and once again we believe it will, it will take
25 the coordinated efforts of our congressional leaders, the

1 government, Department of Defense, state and locals, and
2 very importantly, most importantly, the private sector.

3 The thing that makes this strategy different is
4 it will be a collection of input from all those sectors.
5 It's not going to be something that a half a dozen
6 bureaucrats get together in a room and say, here's our
7 vision of the world to come, and what it's going to take to
8 fix the cyber piece of it. We've had tremendous response
9 from organizations such as this in providing input, meeting
10 with us, sharing your mind share with us in this area, so we
11 can create this living document.

12 And I think that's the other key point I want to
13 bring up relative to this strategy is the living document
14 itself is not something which is going to plug up on the
15 shelf. It will be based, internet based, Web based, it'll
16 be on CitiRom, we'll have the ability as technology changes,
17 as vulnerabilities change, as input changes, we we've had
18 more insights into the interdependencies that we can change
19 as necessary.

20 And lastly, it's a situation where this is not
21 something that just goes to the CIO or to CEO. We've seen a
22 lot of instances now with the proliferation of home users
23 having broad band and DSL and cable modems and we think,
24 well what's that have to do with the power grid? What does
25 this have to do with the chemical industry and the water

1 industry?

2 In reality, what we've seen is they become
3 victims and in turn those victims are used to launch attacks
4 on the rest of the infrastructure.

5 So it's kind of this set up message, if I could,
6 on that. Now in conjunction with that, what we're looking
7 at is some of the priorities that help deal with this.

8 First and foremost, once again the awareness component,
9 identifying the key components that we need to make sure
10 that everyone's aware of. We've created what's known as the
11 National Cyber Security Alliance using those same groups
12 that I mentioned during the preceding comment, the private
13 sector, the high tech industry, the trade associations,
14 government agencies coming together. They actually have a
15 Website called staysafeonline.info, which has a great
16 deal of information for small businesses, consumers, small
17 home office users to how they can do their part to secure
18 things.

19 The next piece is the education. We have a
20 program called "Cybers Corps for Scholarships for Service"
21 with the ability to put people on the pipeline. We have
22 about 450 people on the pipeline now, they're getting
23 graduate and undergraduate training in information security,
24 information assurance, with the intent of coming back and
25 providing that same service to the government for a year or

1 two. If they leave and go to the private sector, we still
2 win, because the private sector being the owners and
3 operators can use the help as well.

4 Information sharing. The ability to take
5 information specifically around things that are being seen
6 at individual companies. We hear the vendors tell us about
7 vulnerabilities and we've got I think a pretty good insight
8 to that. But what are the actual companies saying? Many of
9 the lawyers are concerned about issues around FOIA. If it
10 shares information with the government, then it's an issue
11 they have to be concerned about.

12 Research is a big component of this. Looking at
13 the area beyond national security and market forces, where
14 are the spaces where we need to do some research and
15 development that's not something that one's going to buy or
16 not something directly related to national security?

17 Physical security. We have a tendency to focus
18 on the high tech piece and appropriately so, but there is
19 also the physical security of those key components. The
20 telecom hotels, points appearing that are affected by the IT
21 side of it.

22 The other priority is standards and best
23 practices. We've grown up. This is a relatively new
24 technology. We've grown up in an environment where the
25 normal engineering disciplines that we would see in the

1 electrical industry or the automotive or the space industry,
2 we see those pieces lacking.

3 So looking about certification of IT
4 professionals, looking at some baseline standards on what
5 it means to be secure inside an environment. And in
6 conjunction with that is digital control systems.

1 We have seen a pretty dramatic insight last year
2 in Queensland, Australia where a digital control system was
3 hacked from the Internet, causing the backflow of tens of
4 thousands of gallons of raw, untreated sewage into the
5 streets, hotel lobbies, and parks of one of the cities
6 there.

7 Because increasing we're seeing these digital
8 control devices being attached to the Internet either
9 directly or indirectly through a backend administrative LAN
10 that are now susceptible and vulnerable.

11 And lastly, the future systems that we deal with.
12 As we start to implement the new technologies, we have to
13 have the security as part of the core of business process.
14 Many of us have looked at it, and myself included, in my
15 private sector life as sort of a cost center type basis, but
16 is indeed part of the business process. We have to build it
17 into it, just like we have our HR departments, our financial
18 departments and everything else.

19 Now taking the last couple of minutes here to
20 focus on the strategy specifically, the strategy will have a
21 couple of key components. First and foremost, we will
22 outline a case for action, identifying our vulnerabilities
23 and the potential threats.

24 But I want to touch on the threats piece for a
25 second because we really need to focus more on the

1 vulnerability issue as opposed to trying to imagine what
2 someone could throw against us. If we close the doors and
3 lock the doors on the low-hanging fruit, the easy things to
4 deal with, we can effectively reduce the ability for someone
5 with malintent to affect our critical infrastructure.

6 The strategy is also a multi-level strategy.
7 We're addressing the home users and small businesses. We're
8 addressing the enterprise level folks. We're addressing
9 each one of the critical infrastructures: Banking and
10 finance, transportation, electrical, et cetera, looking at
11 the federal agencies, looking at state and local governments
12 that are very key, looking and very directly at the higher
13 education, providing not only the folks in the pipeline to
14 work in the field, but also the researchers and the Ph.D.s.

15 We're looking at the national structure issues,
16 and of course as we saw with the President's strategy for
17 homeland security, there's a component in there specifically
18 addressing cyber security. It will address on a much
19 broader scale in ours when it comes out in September.

20 And lastly, and definitely not least is the
21 global is the global issues. For the government operations
22 we have in various countries around the world to the
23 operations that we in industry, by which our international
24 corporations rely on that critical infrastructure of other
25 companies, we have to address the issues of critical

1 infrastructure in our national strategy relative to that.

2 And my last comment on this segment is that at
3 the end of each chapter of the strategy, we'll have some key
4 pieces. We will have boxes to talk about, things that we
5 need to have further discussion on. We'll have boxes that
6 talks about some recommendations that we're seeing in our
7 deliberations with the private sector and the other folks,
8 and we'll also have boxes -- some of them will be empty now
9 in the first cut of the strategy -- to reflect the specific
10 programs that we have collectively decided that work best,
11 that we need move on and put these programs into place.

12 So that's sort of the overview of what we're
13 doing at the President's Critical Infrastructure Protection
14 Board. And once again, thank you for the opportunity to
15 meet with you this afternoon.

16 MS. SILVERSTEIN: It's a pleasure to have you
17 here. Thank you very much. In February I think, Chairman
18 Wood was visited by Dick Clark of the President's CIPB, and
19 Mr. Clark sort of, if he were a hand-wringing kind of guy,
20 he would have wrung his hands as he explained to us that out
21 of all of the infrastructures in the U.S., the electricity
22 was perhaps one of the most vulnerable and one of the most
23 critical, and gee, since we were FERC, wasn't there
24 something we could do about this? And we allowed as to how
25 there might be, and it was called Standard Market Design,

1 and that might be a suitable vehicle for standards for cyber
2 security.

3 And with that encouragement, I then took the
4 liberty of forcing myself upon the North American -- say the
5 whole thing for me, Chuck. NERC.

6 MR. NOBLE: North American Electric Reliability
7 Council, NERC.

8 MS. SILVERSTEIN: Thank you. Those guys. And
9 went to the Critical Infrastructure Protection Advisory
10 Group, which is a group of voluntary association of folks
11 from the ISOs, from the RTOs, from the utilities and from
12 the stakeholder groups, and asked them if they would
13 consider working with us to draft security standards for
14 electricity infrastructure more cyber, and more physical to
15 the degree that you need to protect physical, to protect
16 cyber assets and systems.

17 And they debated a great deal and then did us the
18 great favor of saying yes, and then did me the honor of
19 letting me tag along for the ride. And after a very hectic
20 couple of months, we now have for public review for the
21 first time Chuck Noble, who is the head of the drafting
22 group. And I'm pleased to note that there are several other
23 members here.

24 Thank you. You know who you are, from the ISOs,
25 who have been working on this also. Chuck is going to show

1 us what the draft standards are. These will be incorporated
2 in the Standard Market Design NOPR and you all will get to
3 comment on them to your heart's content before they are
4 adopted. Chuck?

5 MR. NOBLE: Thank you. It's my honor to be here
6 on behalf of the North American Electric Reliability Council
7 and to discuss the proposals that we are making to FERC to
8 be incorporated in the upcoming NOPR for SMD. And we're
9 waiting to see if my presentation will be viewable or not.

10 MS. SILVERSTEIN: Lots of people have the
11 handout, so just go with it and we'll see what happens.

12 MR. NOBLE: Okay. We'll move along. I will do
13 more reading from the slide that I have in front of me.

14 (Slide.)

15 MR. NOBLE: As Alison has already said, FERC
16 raised the issue several months ago, and in May, the North
17 American Electric Reliability Council has a work group
18 called the CIP Advisory Group, Critical Infrastructure
19 Protection Advisory Group, reporting to the NERC Board of
20 Trustees.

21 We picked up that task, and I am chairing the
22 self-directed work team to develop the proposal. What was
23 asked of us was to develop a set of minimum daily security
24 standards that can be implemented across the environment to
25 protect those critical assets involved in the market and

1 system operations, to the extent that they do integrate and
2 affect the market as a whole.

3 The general scope of it was going to be primarily
4 on the security standards, addressing as Alison has already
5 said, physical standards to the extent that they are
6 necessary to protect those cyber assets. And we wanted to
7 identify measures to prevent an exploited vulnerability from
8 causing cascading failures throughout the market and grid
9 operations. This does indeed include interconnected SKATA
10 and EMS.

11 (Slide.)

12 MR. NOBLE: But it also takes into consideration
13 differences into not who you are how big you are, but what
14 you do and how you do it, and address scalability along
15 those lines.

16 This is to say, a small participant who maybe
17 does not have a direct Internet presence, no routing access
18 to the Internet, would not be required to implement part of
19 these standards. It just would not apply to them. And this
20 is sensitive for a lot of the smaller entities out there,
21 and we want them to be sure that we are sensitive to those
22 kinds of issues.

23 The proposal is based on standards derived from
24 commonly accepted best practices throughout the industry,
25 including such things as IP SEC, ST SEC, common criteria,

1 the ISO, a 799 standard, et cetera.

2 (Slide.)

3 MR. NOBLE: The initial set will be included in
4 the NOPR coming up for SMD. As a follow-on to this, NERC is
5 agreeing that they will establish an ongoing standards
6 process. They will continue to enhance and maintain over
7 time with changing technology and changing requirements a
8 set of standards that will be in the future referred to by
9 FERC by reference.

10 I think the point that I would like to make here
11 is that FERC agrees that they don't have the security
12 expertise to be doing this themselves, and they're looking
13 to have NERC be the standards devolving body.

14 Just as a quick preview, the standards are going
15 to address a few things.

16 (Slide.)

17 MR. NOBLE: The general purpose, which we've
18 already outlined here the last few minutes. The
19 applicability, which gives a definition of just who it is
20 we're referring to as participants for the purpose of these
21 standards, and how the standards will apply to their
22 interaction with the market and system operations.

23 (Slide.)

24 MR. NOBLE: It also addresses the issue of
25 compliance. As will be stated in the NOPR, it is intended

1 that these standards will become fully compliant and
2 effective as of January 1, 2004. As part of that we will
3 require, or FERC will require, a signed self-certification
4 that the participant is completely certified and completely
5 compliant with all of the standards or document reasons for
6 noncompliance, either because it does not have to comply or
7 they found some other solution which may be acceptable.

8 (Slide.)

9 MR. NOBLE: The standards cover a few basic
10 things. They cover governance, scope, asset control,
11 personnel access control, systems management planning,
12 incident response and reporting, and business continuity.
13 These are basic things that every company should be looking
14 at.

15 Again, some of the smaller entities may not be as
16 encumbered by the systems requirements for example, but we
17 do expect all participants at a minimum to identify someone
18 to be responsible for their security program, to have a
19 documented program in place, to have at least a security
20 policy and basic procedures in place, and to be doing the
21 minimum things like anti-virus protection and authorize the
22 access controls for their systems.

23 (Slide.)

24 MR. NOBLE: The current status as of January
25 17th, a final formal draft copy has gone to the full

1 Critical Infrastructure Protection Advisory Group for NERC
2 for broad review and comment. All comments are due early
3 next week, and our commitment is to have the final proposal
4 submitted to FERC by July 24th. And at that time, we'll
5 work with FERC to get the final verbiage into the NOPR for
6 July 31st.

7 And that's about it at this point in time.

8 COMMISSIONER BROWNELL: Chuck, thanks. I have a
9 couple of questions.

10 MR. NOBLE: Oh, you did get the slides up. I
11 didn't realize.

12 COMMISSIONER BROWNELL: Could you just define a
13 little more clearly what you mean by "smaller entities"?

14 MR. NOBLE: Well, I'll take an example from
15 Massachusetts, a little town called Hudson, Massachusetts, a
16 little municipality. They've got an office with two people
17 that share that office. They share a Macintosh with modem
18 and they dial up the AOL to submit a bid once a day or maybe
19 once a month, okay.

20 I do not expect them to run out and buy a router
21 and install firewall software and do intrusion detection
22 systems and everything else to become compliant. That's
23 someone who in terms of what they're doing and how they're
24 doing it would not need to be compliant with that set of the
25 standards.

1 Where would apply to them, though, and again I
2 expect for all participants, they still need to identify
3 somebody to be responsible for the security program,
4 probably somebody from a management level, okay. I still
5 expect them to have a security policy in place for their
6 organization, and I would still expect them to do some
7 minimal training and access control around who's authorized
8 to access that Macintosh and to assure us that it's kept in
9 a locked room when nobody's around, et cetera.

10 Those are really small cost issues and should not
11 be an issue for them.

12 COMMISSIONER BROWNELL: But your proposal will
13 take a shot at defining it in more than an anecdotal way?

14 MR. NOBLE: Yes.

15 COMMISSIONER BROWNELL: That there will be some
16 measure so we're not debating that forever?

17 MR. NOBLE: Yes.

18 COMMISSIONER BROWNELL: Okay.

19 MR. NOBLE: With roughly 15 minutes, I did not
20 prepare to come here to debate each individual proposal.

21 COMMISSIONER BROWNELL: No, no. I just want to
22 get a handle on that. Self-certification, do you plan to
23 have some kind of an audit, random audit? Would you expect
24 us to do that?

25 MR. NOBLE: That is something I think we need to

1 work out.

2 COMMISSIONER BROWNELL: Okay. And governance?

3 Governance of what? Governance of the organization in case
4 of an emergency?

5 MR. NOBLE: Governance briefly is saying that
6 they will anoint someone to be responsible at a management
7 level for their security program to ensure they have a
8 security policy, to ensure all these other things are
9 compliant.

10 COMMISSIONER BROWNELL: Okay.

11 MR. NOBLE: Or they have documentation as to why
12 not.

13 COMMISSIONER BROWNELL: Okay. Thanks.

14 MS. SILVERSTEIN: We have been walking a very
15 fine line in designing and defining what these are supposed
16 to do. We started by saying this is a minimum daily adult
17 requirement. It is what using available practices and
18 technologies anyone who has the capability to be used as a
19 way to hurt the grid and operations needs to do to protect
20 other people from their cyber assets, as well as to protect
21 themselves.

22 But we tried to hard to look for what is the
23 minimum that can be done that will achieve some meaningful
24 level of protection and yet not create barriers to entry or
25 significantly increased the costs of operation for smaller

1 participants in the market. So we are walking a fairly
2 delicate balance there.

3 MR. SCHMIDT: Alison, if I may just add
4 something. What I'm hearing here from Chuck saying is
5 something we salute and we applaud the efforts to do this,
6 and also to sort of frame it that this is totally consistent
7 across every critical infrastructure we've seen: Issues
8 around authentication and access control, issues around best
9 practices, issues around even some fundamental policies
10 depending upon the size of the organization, so we really
11 support that this is a good way to look at the thing and it
12 helps us in other industries as well.

13 MS. SILVERSTEIN: I'm really glad to hear that
14 because we worked with your staff a lot to get to this
15 point. Thank you.

16 MR. NOBLE: And if I could just add to that, I
17 want to make sure everybody understands that this is just
18 the first step for both FERC and for NERC, okay.

19 As I said, this will become an ongoing standards
20 evolution process. I expect more detailed standards to come
21 out of the NERC body itself over time, and we will continue
22 to grow that as the technology changes, as requirements
23 change, as new vulnerabilities are identified through the
24 change of technology, et cetera.

25 So this is just the beginning for us.

1 COMMISSIONER BROWNELL: And in your working
2 group, is there representation from the ISO community
3 itself, or are you working with the companies?

4 MR. NOBLE: First, let me talk briefly about the
5 Critical Infrastructure Protection Advisory Group in NERC,
6 okay. It is made up of representatives from the initial
7 four -- excuse me, ten reliability regions, okay. It has
8 representation from most of the ISOs RTOs. It has
9 representations from organizations such as EEI, NRECA, APPA,
10 et cetera.

11 We have reached out to both the primary ISO and
12 market organizations. We have reached out particularly
13 through the EEI, to the asset owners, and they brought a lot
14 to this table with regards to physical security, and also
15 with the other industry associations who, by the way, do
16 represent some of those very small entities and did have
17 some concerns that we did try to accommodate.

18 MS. SILVERSTEIN: One of the things that as we go
19 through the process of receiving public comment on the
20 standards, do us a favor and focus less on the question of
21 whether FERC should be setting standards and just bite that
22 bullet and move on to are these the right standards.

23 But know that the electricity sector appears to
24 be the first one for which standards for cyber in this day
25 and age are being set. There are some for health care and

1 some for finance that were set in a different time for a
2 different purpose, but this is the first post-9/11 set of
3 cyber security standards to be undertaken, and it is our
4 expectation that they will serve this approach, as well as
5 these technology standards themselves will serve as a model
6 for other industries and sectors. So we encourage you to
7 help us get this right and to understand the purpose for
8 which they are being done.

9 Copies are in the back of the room of the
10 document itself, and we'll put it up on FERC's Web site this
11 afternoon. This is a draft. Only folks who are in the NERC
12 group are the only ones I think from whom we're taking
13 comment at this time to change the draft, but everybody's
14 welcome to comment on a notice of proposed regulation, and I
15 don't expect that you all will be shy.

16 So let us know what you think and help us make
17 this work for the sector. And please, as you go through
18 serving this industry as software vendors, please build
19 security integral to your software so that we don't have to
20 spend extra money fixing it later to keep it from hurting
21 the systems as a whole.

22 MR. NOBLE: Okay. And if anybody is interested,
23 I have assurance from NERC that after today, sometime
24 tomorrow morning, a copy of this presentation will be
25 available from their Web site as well if anybody would like

1 a copy of the slides to work with their management.

2 COMMISSIONER BROWNELL: Thank you both for
3 coming. I know you have busy day jobs. Howard, we
4 appreciate the work you've done, and I think the
5 inclusiveness that you have shown in terms of developing
6 responses to very difficult and challenging issues. So,
7 thank you for sharing the time with us today.

8 MR. SCHMIDT: Thank you.

9 MS. SILVERSTEIN: And my thanks to you both and
10 my thanks especially to the NERC Critical Infrastructure
11 Protection Group for working so hard on these draft
12 standards and for putting up with me. I've enjoyed it
13 greatly. Thank you.

14 COMMISSIONER BROWNELL: We thank you for putting
15 up with her too.

16 (Laughter.)

17 MS. SILVERSTEIN: If you're on the next panel,
18 come on down.

19 (Pause.)

20 MR. O'NEILL: Well, let's get started. This
21 panel is composed of ISOs who have to implement the Standard
22 Market Design and who have to use the vendor's software that
23 we heard about this morning. And what we would like to hear
24 from this panel today and to have a discussion on is their
25 problems with implementing software. Obviously this is a

1 rather new venture here. The oldest ISO I think is what,
2 six years old now? Or four or five years old.

3 So we have experiences. We're making progress.
4 And we'd just like to hear from you about the problems
5 you've had and how you see us solving them in the Standard
6 Market Design, what FERC should do, what the ISO should do,
7 and problems that you may see coming with the coming of
8 larger RTOs or larger ISOs.

9 So let's I guess go right across the board and
10 start with a nonregulated --

11 MS. SILVERSTEIN: They're regulated, just by
12 someone else.

13 (Laughter.)

14 MR. O'NEILL: I didn't put the period in the
15 sentence. Nonregulated by FERC, a nonregulated by FERC RTO,
16 or ISO, sorry ERCOT.

17 MS. BROADRICK: Certainly with some experience
18 with the Commission here. I'm Cherie Broadrick with ERCOT.
19 I am relatively new to this position and filling in for Sam
20 Jones today.

21 We did our software interface with an XML
22 interface through a Web-based application, and we issued our
23 XML standards to the market participants, and then they
24 developed their interface with us through those standards.

25 Actually, I don't really have bad war stories.

1 I'm going to be very short here. We didn't have a whole lot
2 of problems. I'm going to talk more on the people side of
3 the business where we did see our problems, and that's in
4 expectation setting and in education. And I heard a little
5 bit about that this morning, and I don't think that we can
6 minimize that aspect.

7 Education for the market participants and the
8 staff of an ISO from the software vendors is integral. And
9 I think our experience, and especially I ran the retail side
10 of the business for two years, and my experience there is
11 that if we don't publish our standards to one another and
12 make visible how we calculate things, there's going to be a
13 lot of hiccoughs.

14 So I would encourage definitely that whoever
15 comes into the ISO to put software in place also has a big
16 task in education and the staff and the market participants
17 also. I believe visibility is integral to a seamless change
18 in anything that we do in the way that we do business.

19 So that's pretty much what I have to say.

20 MR. O'NEILL: Dave?

21 MR. LA PLANTE: We're in the process of
22 implementing our second market system. I don't want to
23 dwell on the first one. I don't think it would be
24 productive. But we are actually trying to do the first
25 Standard Market Design implementation, if you will.

1 We decided to implement the PJM market design and
2 the PJM software. So I think what we're learning here may
3 be helpful as the Commission puts a Standard Market Design
4 NOPR together.

5 The reasons we did it are I think some of the
6 same reasons that are driving you to do it, which was to
7 reduce the time to implement LMP in multi-settlement, reduce
8 our schedule and development risks, and to reduce the costs.

9 To date, we've been fairly successful. It has
10 met those objectives. The software has come in from the
11 vendor on time. It's worked pretty well. So it has been
12 positive. Of course, we don't really know how positive it
13 is until we put the market live and see if we can actually
14 run the market and the systems with it. But to date, the
15 effort to standardize has shown the benefits we thought it
16 would.

17 More specifically, some of the benefits were the
18 market design process became much clearer. Back when New
19 England implemented its first market in '96 and '97, coming
20 together on what the market design was was awful. People
21 were in a room. They couldn't get together on the design at
22 all. Having made a commitment to a design up front
23 streamlined that process and made it possible to move ahead.

24 And another benefit of an existing market design,
25 especially one that works, is the market design is tried and

1 it's much more likely that it's going to work. So that
2 certainly lessens the risk and I think is one of the reasons
3 the Commission is trying to do a Standard Market Design.

4 And we've also been able to add some features to
5 the original design to deal with some issues peculiar to New
6 England, and we added losses to the PJM platform. So we've
7 been able to build on it, and I think that's something that
8 can be shared with other people that use the same software.

9 MR. O'NEILL: Dave, when you say losses, do you
10 mean marginal losses?

11 MR. LA PLANTE: I do mean marginal losses. And
12 they'll be part of the dispatch and part of the settlements,
13 and we're going to allocate them in a fair way.

14 MS. SILVERSTEIN: As opposed to an unfair
15 allocation?

16 (Laughter.)

17 MR. LA PLANTE: Well, I noticed that there was a
18 case in front of the courts dealing with the allocation of
19 loses, so we looked at that and tried to take that into
20 account in our rules.

21 MR. O'NEILL: Doing it right isn't always easy.

22 MR. LA PLANTE: No. Some of the risks and issues
23 we see from a Standard Market Design implementation on the
24 market side is that there are operational issues that PJM
25 doesn't face that we face. In particular, the way that we

1 use reserves on thermal units is different than the way PJM
2 does. So some of the real time dispatch didn't have reserve
3 constraints in it. We're going to try to run our system
4 without that. That's something that we'll have to see how
5 it works.

6 And there's also a change in operational
7 practices that may be needed or terminology so that there is
8 a conversion process as you standardize the transition
9 affects the whole enterprise from the operators to the
10 businesspeople to the market design people.

11 Now in terms of software implementation, some of
12 the benefits were -- one of the big benefits for us and what
13 influenced our decision is we had the same vendor as PJM did
14 for some of their components, so that made it easier for us.

15 And a big benefit that may not pop out right away
16 is if you're using existing software or a standard, you
17 don't have to write a detailed functional requirements
18 document, which is a very time consuming process for
19 something as complicated as a market system. And the better
20 the software documentation, the easier the implementation is
21 going to be.

22 I'd like to mention one area that hasn't really
23 been mentioned too much yet, which is settlement software.
24 You have to operate these markets, and we focused and I
25 think most of the thought on market software goes to the

1 algorithms that run the markets in the FTRs.

2 You also need to settle it. Settlement systems
3 to date have been very implementation-specific, and that may
4 continue for a while. I think it's possible to put a
5 settlement engine together, and I think some vendors like
6 LodeStar and others may have done that. But the settlement
7 is integrated with the meter data, and the processes is that
8 the transmission owners and the meter readers have for doing
9 that.

10 So settlements is a bit messier. I think SMD may
11 facilitate that because hopefully the data elements are the
12 same and the market design is the same, so the settlement
13 processes you get similar. But that's something that I
14 think may come up in the NOPR and is something to think
15 about as we move forward.

16 And related to settlements is publishing
17 requirements and software, how you get the results of the
18 market to the market. And if that's standardized, that's
19 going to help everybody, because now all the market
20 participants would have one set of data they're going after
21 or one set of information. That's another area that's
22 helpful.

23 In terms of maintaining standardization, this is
24 going to be a huge challenge. As I said, we're adopting the
25 PJM software, but even before we've gone live, we've had to

1 diverge from it, not in significant ways, but in ways that
2 as they accumulate you'll have systems that are different
3 over a period of years.

4 PJM's approach to market monitoring is very
5 different than New England's. That flows back into the
6 market and into the software design, so you end up with
7 things that aren't quite the same.

8 Our observation from that is that some sort of
9 body that agrees upon changes and differences is needed so a
10 standard can in fact become a standard.

11 Is it so unimportant that no one cares if it's
12 different or is that an important decision that people have
13 to make? And that's I think another part of the Standard
14 Market Design that's going to be an important decision and
15 not an easy one, which is how much detail does the Standard
16 Market Design have in it?

17 The more detail obviously the easier it is to
18 keep the standard. On the other hand, who could manage --
19 can one entity manage all the detail that would be needed to
20 effectively do it? And trying to balance how much detail
21 can be effectively managed by one body with the need to have
22 a standard market that's truly standard is going to be a
23 difficult balancing act. But I think it's very important.

24 COMMISSIONER BROWNELL: Who should serve as such
25 a standard-setting body? Or how do we go about creating

1 that?

2 MR. LA PLANTE: That's a good question. I think
3 NAESB has been created to do certain things, but I think
4 it's difficult for market participants to come together on
5 issues that affect money. So those truly belong in the
6 Commission's hands.

7 As the ISOs and RTOs, we've been sort of in the
8 middle on a number of these issues and may be able to work
9 in that role of coming up with reasonable proposals for
10 solutions that affect money as sort of an intermediary
11 between the business practices that NAESB maybe working with
12 and the Commission's role of policy and rules.

13 So if there's a gap there, I think the ISOs and
14 RTOs may be a good entity to use to fill that gap.

15 COMMISSIONER BROWNELL: Although in another
16 context, Jim Torgerson from the Midwest ISO brought up the
17 same issue of these nuanced differences and different timing
18 issues that in fact undermine the very concept of Standard
19 Market Design. And he called for some similar kind of
20 higher body to take a look at this and make the rules around
21 it.

22 So maybe it's a group of the ISOs. I'm just not
23 sure. But I think we need to get there sooner rather than
24 later, the more I hear, and I think we heard some things
25 this morning that would suggest that as well.

1 MR. LA PLANTE: Right. And I think comments on
2 the SMD NOPR will help us hopefully focus on that.

3 (Pause.)

4 I had a couple of comments that really were
5 related to what happened, the discussion this morning, is
6 the level of standardization should allow the vendors the
7 ability to innovate. Otherwise, you're not going to get the
8 number of vendors you need and the number of products that
9 we need.

10 And in terms of software standards and creating
11 RTOs, there was a lot of discussion today and actually quite
12 a bit of discussion yesterday about the scale and the fact
13 that the software is essential to have larger RTOs.

14 I think there was a whole set of operational
15 issues associated with increasing the RTOs that have to be
16 addressed as well. If we make large RTOs, it's going to
17 require more complex sort of vertical structure to manage
18 the grid. If you had one manager for the whole Eastern
19 Interconnection, you'd have to have a whole number of sub-
20 satellites that were doing a lot of the work to assure that
21 the systems operated reliably.

22 So as we try to expand it in one direction
23 horizontally, we're going to need to do a bunch of vertical
24 integration and coordination for reliability. And I think
25 the PJM MISO design relies on the existing utilities to do a

1 lot of that sort of detailed operation.

2 I had a number of other slides on
3 standardization, but they're really repetitive with what
4 went on this morning.

5 Thank you.

6 MR. OTT: Hi. I'm Andy Ott from PJM. I'm going
7 to talk a little bit about some of our experiences as we've
8 evolved over the years from a software point of view.

9 Some of our experiences really were based on the
10 way PJM actually evolved. It was more a staged approach.
11 We had a real time market starting in '98 out of the
12 transmission rights market in '99 out of the day ahead
13 market in 2000, et cetera. So as we were growing.

14 One thing we found was that as we grew
15 the products if you will and the markets, as we searched for
16 ways to acquire the software, one of the issues that we
17 faced in just growth was we actually have multiple vendors
18 for different parts of our market.

19 So actually getting the data, the technical model
20 data in between was actually obviously not impossible,
21 because we did it. But it took -- it added five months on
22 to our schedule to actually do the conversion, because it
23 was something that had to be automated so that we could
24 convert the data from one to the other. So it wasn't an
25 easy way to do it.

1 So I think that that kind of challenge has helped
2 us to sort of point our focus for the future in really
3 trying to look at how do we get data. And we're talking
4 about the very technical data underneath that the software
5 needs between two what I'll call different vendors.

6 And I think from our perspective, we solved the
7 problem uniquely or once for that specific instance. But I
8 think solving that problem globally is something we're
9 looking for.

10 I think something related to that, if you think
11 about challenges, if you think about our challenges, which
12 are I guess important to me, but to my participants, what's
13 really important is their challenges. In other words, when
14 I rolled this stuff out, what was really their issues or
15 their problems.

16 I think one of the issues that we have, PJM has
17 tried to do a decent job in trying to keep pace with is
18 really the issue of data transparency or transparency of
19 information to the participants.

20 As we all know, these markets live on incentives,
21 and these markets live on the consistency between what
22 you're asking the market participant to do or the
23 consistency between the dispatch and the pricing systems.
24 And again, a lot of that is related to the confidence that
25 people have in markets.

1 So when I need to put data out, data models out
2 to the participants to allow them to verify or validate on
3 their own, using their own people and vendors, et cetera, to
4 run these models and try to make some sense out of them.

5 That's the whole, you know, the black box thing
6 where, you know, is this thing really something you can't
7 understand? And the answer is, well, if you're given the
8 data, such that it's transparent, or a lot of dataflow is
9 available to the participants, then it breaks down a lot of
10 that while I'll call suspicion or whatever.

11 One of the challenges we've had is it's very
12 difficult for us to put out the detailed data of the market
13 or the power flow, because there's no standard data format.
14 In other words, we have a standard for power flow. You have
15 the PTI or whatever. But in these models, we actually use
16 the more EMS-style model, the breaker type model. It is a
17 very, very detailed level of model, which is not the same as
18 the level of model that they use in transmission planning,
19 for instance.

20 But in the actual market and system operations,
21 you need a more detailed. There's really no good standard
22 to transport data. And I think that's one of the first
23 things we need to solidify. And I think we've talked about
24 that kind of -- it's really a data format type standard
25 that's needed. I don't think you need a standard in the

1 actual software modules, because that again would discourage
2 invasion, but it's really how do you get the data between
3 the two.

4 One of the other things we found with the
5 participants is as we grew, you know, we were developing
6 sort of as we went, how we're going to standardize our own
7 Web interface or user interfaces for our participants. The
8 newer ones we have would have XML. The old ones didn't have
9 XML. They had some other format.

10 So as we look forward again to the future, we
11 need to go back and make sure that those are standard. But
12 beyond that, I think, as an industry, we suffer from a lack
13 of the terminology. And again I call it an FTR, somebody
14 else calls it a TCC. You know, for transmission, right,
15 that's ridiculous. It just makes it a lot harder for the
16 participants to keep up.

17 And again, it really costs them more money
18 because they have to train themselves twice on using these
19 systems. So really I see that as, if you're looking for
20 sort of a place where the largest benefit is going to come,
21 I think the largest benefit is going to come -- there are a
22 few RTOs, ISOs. There are many more market participants.
23 So if there's standardization we can do to make it easier
24 for market participants to spend less money, I think that's
25 really the area that you can reap the most benefit from a

1 cost point of view.

2 Because the RTOs' implementation cost we found is
3 one thing. But every time I make a change, my 200 members
4 may need to make that change 200 times to respond to mine.
5 If they have to do that for every market they participate
6 in, that could be much more expensive than you realize.

7 I'll stop there.

8 MS. SILVERSTEIN: Well, you know, the whole point
9 of us doing a Standard Market Design NOPR is to get
10 everybody to use the same words in a discussion.

11 MR. OTT: Formats.

12 MS. SILVERSTEIN: So we will all retrain each
13 other simultaneously in a common terminology so that if we
14 remain confused, it will be about the concepts rather than
15 what the words mean.

16 MR. OTT: Very good. Data formats too.

17 MS. SILVERSTEIN: That's on the second day.

18 MS. BROADRICK: That will be shocking to Texans.

19 (Laughter.)

20 MS. SILVERSTEIN: Well, Texans don't have to do
21 it that way, within ERCOT of course. But actually we just
22 brought all the ERCOT terminology up with us and we're
23 retraining the rest of the country to do it the Texas way.

24 COMMISSIONER BROWNELL: In your dreams, Alison.

25 (Laughter.)

1 MR. PALIZA: I'm Roberto Paliza with the Midwest
2 ISO. And I'm going to talk about the MISO markets
3 implementation effort. Our project in the Midwest is
4 underway, and the target date for implementation of the
5 markets is late 2003.

6 The initial effort is focused on combining and
7 establishing the markets on the combined MISO, SPP
8 footprint. And some statistics about this market, it will
9 have 150 gigawatts peak load, 144,000 miles of transmission
10 lines. More than 20 states will be involved, and these
11 markets will include at least five transcos. ATC, Michigan,
12 ITC, TransLink America.

13 This is the first step in establishment of what
14 we have called the single market MISO-PJM-SPP. The schedule
15 for implementation is 2005.

16 So it's a large scale market. Some of the main
17 characteristics of this particular project is that we are
18 starting from scratch in regard to energy markets, because
19 the Midwest doesn't have a centralized market at this point
20 in time. So there are no legacy systems that we have to
21 deal with.

22 However, we have -- our base system that is
23 basically the EMS that we use for real time and monitoring
24 our security.

25 Another important characteristic of this project

1 is a multi-vendor project. We have a vendor for the day
2 ahead market, the real time market, another vendor for the
3 financial transmission rights, settlements and then another
4 one for scheduling. So this will pose the challenge of
5 interoperability among all these vendors and integration.

6 We are also looking beyond the initial
7 implementation. We will have to deal with maintenance of
8 the system and future enhancements since we are dealing with
9 several vendors, several databases and several pieces of
10 software.

11 The market model size is transmission-wise more
12 than 30,000 buses, power flow buses; 3,000 to 4,000
13 generators. And it includes part of MAIN, MAPP, SPP and
14 ERCA regions. These, as you can see, will pose a unique
15 operational challenge when we talk about five minutes
16 centralized dispatch.

17 In addition to that, a very important aspect in
18 this project is to make sure that we build a system that we
19 can coordinate with other RTOs such as PJM and those that
20 are going to implement the Standard Market Design.

21 Now focusing on multi-vendor interoperability, we
22 believe that the standards in this area are needed, that it
23 will foster competition resulting in better products to
24 build and upgrade a market system in a cost effective way.

25 And I would like to focus on a particular aspect

1 of this interoperability amongst vendors, and that is model
2 exchange. When I talk about model exchange, I'm not talking
3 only about a transmission system model. I'm talking about
4 the market model. I'm talking about the dynamic data that is
5 needed in order to support these models.

6 And we need to take into consideration offline
7 type of data that needs to be exchanged as well as the real
8 time data. So it adds another level of complexity.

9 We support the common information model, CIM, to
10 be used as a standard for exchange these power system models
11 and any enhancement that is needed in order to support these
12 markets data exchange.

13 And in that regard, it is important that we
14 identify the entity who will be responsible to administer
15 this system. It could be a EPRI or IEEE in coordination
16 with the users. It also is important to identify who is
17 going to enforce these standards. NERC has done it in the
18 past in certain aspects of the industry, but I think the
19 customers, especially RTOs, need to be fully engaged in
20 supporting the enforcement of these standards.

21 Other areas that standards could be very helpful
22 are the common application programming and using interface,
23 a standard data exchange, interchange to unload and download
24 data such as XML.

25 Now when we talk about implementation of large

1 markets such as the Midwest, we have several aspects that we
2 need to take into consideration. One of those is the
3 operational challenge of managing such a market on a five-
4 minute interval. There are numerous transmission
5 constraints and contingencies that basically makes the
6 operation very complex, numerous dispatch patterns and
7 generation constraints.

8 In our case, we need to take into account a
9 multi-control area structure, and the multiple NERC
10 reliability regions that are included.

11 Now from the operational challenge, we also need
12 to look at the system performance. And when I talk about
13 system performance, I'm only talking about the application,
14 the processing power, the number crunching, such as security
15 constraint dispatch and security constraint commitment. But
16 in addition to that, we need to take into consideration the
17 data collection, distribution, storage and retrieval that
18 could be significant in regards to performance.

19 Another aspect of implementing this large market
20 is that it hasn't been done before. It is an immature
21 marketplace. There is no experience in administering such
22 a large market. And we know from the Northeast RTOs'
23 experience that the overall process is not fully automated,
24 and the operators play a key role in this operation.

25 Other aspects that are of importance for

1 implementing these large markets are testing of the software
2 and hardware. There are numerous logical paths that need to
3 be tested, including complex processes. Marketing
4 monitoring is going to be a challenge. And as David
5 mentioned before, market settlements. Processing and
6 verification of invoicing and billing. This is also a very
7 important aspect.

8 So in summary, we feel that they key aspects to
9 ensure a successful implementation of large markets can be
10 achieved by a well defined requirements process. As Andy
11 mentioned before, implementing the project in stages, use of
12 industry standards, having a well rounded project team with
13 industry experience, establish a well defined and in-depth
14 training programs, a high degree of system automation is
15 required, and automater error checking and debugging is also
16 required.

17 Thank you.

18
19
20
21
22
23
24
25

1 MS. SILVERSTEIN: Thank you. Mr. Watkins?

2 MR. WATKINS: I don't represent an ISO at this
3 point, but actually I represent one working one and two
4 wanabees at this point, so that's West Connect in the desert
5 Southwest area, the California ISO, which we all know and
6 love, and the RTO West, which is in the Northwest.

7 About a year and a half ago or so, there was a
8 group that gathered called the Seams Steering Committee.
9 It's now called the Seams Steering Committee of the Western
10 Interconnection, SSCWI, and they thought, you know, we're
11 building all this stuff, and we're all doing our own thing
12 and it's become increasingly apparent that markets and
13 commercial business are a big deal, and us working together.

14 And also we figured, you know, we're doing a lot
15 of different things, and maybe we could work together on
16 some things. And so they asked for us to investigate some
17 things, and we formed a group called the Common Systems
18 Interface Coordination Group, which we finally referred to
19 as seasick (CSICG), and it's appropriate many times.

20 So what we've been doing is putting together --
21 it's an open group of members of the three potential RTOs,
22 and also has a lot of vendors because, of course, we're
23 talking about systems, and we're talking about efficiencies
24 of systems and using backup control centers for each other,
25 and a whole bunch of things like that, which eventually

1 involved a lot of systems and money and so on.

2 So it's actually had very high talent and very
3 good input from multiple parties. So I come with that
4 perspective today, and want to talk, actually, about
5 something we've been calling electric grease. There's a
6 handout -- this isn't what yours looks like, but it has two
7 sides and the front, and it would really help if you could
8 follow that, because there are some pictures I want to spend
9 a few minutes with on that.

10 So, SMD, as we've talked about, is really about
11 the what. It's got to slides on the front and it has a
12 funny little circle that says seasick on the top left. I
13 really do want you to be looking at it, so if you don't have
14 it, it was in the handouts in the back.

15 MS. SILVERSTEIN: You do win the acronym award
16 for the day.

17 MR. WATKINS: We also have a subgroup of that
18 called BAD for the Business Architecture Development Group.
19 I know you didn't want to know that. And the group -- never
20 mind -- there's another group, but you don't want to hear
21 about it.

22 Okay, so there's another group that once the BAD
23 has done their thing, that we'll design requirements and
24 protocols, which is RAPP, so we have a seasick, BAD, RAPP.

25 MS. SILVERSTEIN: We were hoping for the good,

1 the bad, and the ugly.

2 MR. WATKINS: Well, you know, we're working on
3 that, and others have thought of all kinds of things.

4 So, we started talking -- SMD is about the what,
5 right? It's about what the business stuff has to look like,
6 how it has to function, what it has to do.

7 And that's great, but the problem is that it's
8 the detail, right; it's the devil is in the details, and how
9 do you make this happen?

10 And the thought was that there have actually been
11 a number of efforts, a number of things that have been good
12 efforts to look at single systems that would allow
13 interactions or transactions to happen across the grid. And
14 as OASIS came in '95 and '96, the idea was that we'd do this
15 tagging thing, but we'd also have these transaction systems
16 where everyone could talk and work it all the way through,
17 and that somewhat got set aside, because of all the
18 difficulties of trying to do our new, increasingly complex
19 business, using our old tools, largely for scheduling and so
20 on.

21 So, we've started thinking a lot about this, and
22 so what I'm going to talk about is -- we call it electric
23 grease, just because the idea is to grease the whole
24 transaction process. And what we're going to talk about is
25 a track to enable a comprehensive western wholesale electric

1 transaction system.

2 And I say western because that's our scope, but I
3 think it's a higher need and a wider need. And so what
4 SSCWI is about and the Western Area Connection is we're
5 going to have our plan for the start to have three
6 independent RTOs, but what we know is deeply important is to
7 have a single market interface.

8 So to the outside user, it looks like a single
9 RTO, so to speak, not a single RTO, but from the business
10 point of view, it is a virtual RTO. So skip the second page
11 here and move to the third, which has a diagram. It says
12 Functional Model on the top.

13 And the first thing I'm going to tell you is that
14 this isn't new, so when you look at it and say we thought of
15 this, I know you thought of it. But the key is that there
16 are a bunch of functions that we have that make the market
17 operate, and there are other boxes you could put in here.
18 You could break some of these out; you could put some other
19 things in here, but basically it takes a transaction all the
20 way through from this buy-and-sell, which is really about --
21 it's about bidding things in or any way you buy or sell
22 energy -- long-term, short-term, however you do it, however
23 you transact energy between buyers and sellers, it happens
24 up in that box, which I know has real-time, day-ahead, and
25 so on and long-term components.

1 And then there is the whole issue of transmission
2 rights, whatever you call them, how do you get them, what
3 are the third-party markets for them? There's a whole bunch
4 of stuff wrapped in there.

5 Then there is the market systems, which is
6 sometimes part of the rights, which is how do handle your
7 congestion management? How do you make all this work?

8 And now here comes my issue, because a lot of
9 this is commercial and it has to be commercial. The power
10 systems are there to move energy, but real-time operations
11 is kind of a mess right now. And it's not that we're not
12 operating reliably, but the problem is that entities like
13 the California ISO and Bonneville Power at this point,
14 handle hundreds and hundreds and hundreds of transactions
15 every hour, and if you have to go cut a whole bunch of stuff
16 like this week we've had fires along the Pacific interties,
17 California is short of energy, which is, of course, not new
18 in the summer when you have a heat wave going through, and
19 fires have been taking our lines down, the AC lines, so what
20 happens in real-time, you have to cut a bunch of schedules.
21 That's how you do your business.

22 Well, in real-time, you can't cut all the
23 schedules. And what we end up with sometimes -- we do get
24 them down often by just agreeing to move our controllers and
25 then match the schedules later, because you can't go and say

1 I want to cut all these schedules, load; you've got to find
2 another generator right now.

3 Generator, you've got to shut down, and you need
4 to do it right now, within ten minutes. It's not possible;
5 it doesn't happen the way the transaction systems are
6 formed.

7 Tagging 1-7 gets us closer, but it still doesn't
8 tap back to there, so we have a real-time operation, and
9 that needs something. And you also have these other parts
10 down below which are mostly after-the-fact, which is how
11 you're handling all your metering, which is getting what
12 your actuals are, compared to what you thought you were
13 doing, settling all that between you.

14 And then why not transfer your funds
15 electronically, too. There's a huge value of money as it
16 sits, and it's often sitting in the wrong places, sometimes
17 for months, because it takes a long time to settle all this
18 stuff -- 40 days at best, you know, in some of our entities
19 that I know of.

20 So the thought of this picture is -- and it's
21 what we've been talking about all day today, but it's bigger
22 and wider; is that we really need something that covers the
23 transaction from the very inception of an energy deal, all
24 the way through to the point where you move funds to pay
25 people off, and all the pieces in between.

1 People have done this, by the way. There was a
2 software vendor in '94 that actually did a proprietary
3 system that covered most of this. It was before
4 transmission and energy was separated, but these are not
5 complete pipe dreams.

6 So the proposal of this model is -- and, again,
7 this isn't new; it's what we've been talking about -- is
8 that you need a common information interface, and when we
9 refer to this, I don't think we're talking about standards
10 that say you have to say this and you have to do this in
11 your protocols; you have to use CIM; you have to do
12 whatever. It's really saying that whatever you do, you have
13 to have a model that will allow any of these boxes and maybe
14 subsets of these boxes, to plug in.

15 So any vendor -- some of these are dominated by
16 certain vendors. The idea is, any vendor, anybody that
17 could conceive a way of doing it and someone would buy it,
18 could go plug in their piece of this, and when they talked
19 from their box, which could have whatever they wanted in it,
20 because it's a black box, but it had to do a certain
21 function, when it talked to these other systems, they would
22 all understand what it was saying.

23 So this is our basic model, and so it's a
24 functional model; it's not new. What's really important, I
25 think, to put on there -- and I know it's obvious, but I'm

1 going to say it anyway -- is these little ovals on each side
2 are really important.

3 One is, we have a whole bunch of legacy systems
4 and components and there are a lot of non-jurisdictionals
5 out there, right? And there are others that will play in a
6 little different ways, like a certain state. And so what
7 happens is that you really have to have hooks for your
8 interfaces to these legacy systems. This is not minor.
9 There's a lot of preexisting contracts and ways business has
10 been done that has to be accommodated.

11 So we've put that and that has to attach to this
12 bus, so we've got to find a way of doing that. And I'm
13 going to talk about the way in a minute.

14 The other part is -- and this is really big for
15 you guys; I know it is, and it's big for us, too. On the
16 other side is a market monitor, because if you don't have
17 transparency of data and all data looking the same and
18 having the same hooks, it's really hard to know what's going
19 on.

20 But if you do, and everything is defined and
21 everything has been told what it means and where it goes,
22 you've got transparency and you can see everything as a
23 market monitor, and I think that's really important. The
24 other part is, we have something out there called
25 reliability coordinators, and you know they are really

1 important, because they watch over the larger part of the
2 system. And suddenly they have a lot more data about
3 schedules, and that's important.

4 The last thing I want to say on this is about
5 that upper bar that sits there. And I think when we've
6 talked, we've figured out that it might be bad to be super
7 prescriptive about how every display should look, how every
8 word should be said and all that.

9 But we do recognize that there is a problem that
10 when people get to websites or they get to certain
11 connections, they really want to see similar things. So the
12 thought is, there probably should be some idea of standard
13 interfaces, but don't go heavy on standard, like here's the
14 picture, draw it like this, but find some way of making sure
15 they are coordinated.

16 And so let me talk -- I'm not going to get to the
17 good picture yet, but I'll talk about value for just a
18 second. One is, we really do want a virtual, single,
19 commercial interface, not a storefront that has three shops
20 in it, where you go in and you have to find your way around
21 the different pieces done. It needs to look like one thing.

22 The market needs to be efficient, and when we do
23 this model we've just talked about, if we have common
24 systems -- right now, people can do better things because
25 they have better electronic systems to go query everybody's

1 OASIS. Some are really good at getting information out.
2 Others aren't as good.

3 The ones who can somehow find it do better in the
4 market. You need equal playing fields, level playing
5 fields, and this does that.

6 The other part, though, is, we have a lot of
7 transaction costs, so this a bad example. But Bonneville
8 has like six real-time transmission schedulers sitting
9 there, and that's way too many, right? But the problem is,
10 they need it to handle all the transactions.

11 But when you have that many people working on the
12 same thing, you've got problems. Sometimes you'll miss;
13 sometimes two people think they're doing the same thing, and
14 so on. And I don't think Bonneville does any worse than
15 anyone else.

16 The main point is that we need some system that
17 will tie all that together, make sure it's all happening
18 electronically, so we're mainly just watching, instead of
19 having huge human labor involved in doing this. Errors get
20 introduced when you have human labor, so it's efficient, a
21 more efficient market.

22 I already talked about monitoring for the market
23 and reliability. But listen to this one, because this is
24 pretty cool: We need something that will create high
25 business agility.

1 Things are going to change. People are going to
2 have new ideas. You know that we're talking about a five-
3 minute market now, and with our current systems, we can't do
4 that hardly, right? You can build specials that will do it
5 in certain areas to do that, but it's difficult.

6 California is doing some of that stuff now
7 because they need to. I mean, there's a need to do this.
8 I've heard talk of continuous scheduling, right, which makes
9 operators like me go crazy to think about continually
10 setting ramp rates and mark schedules that run all kinds of
11 hours.

12 But the fact is, if you created a good open
13 systems model and made it work, you could do anything you
14 could conceive of and it would be reliable. It would have
15 to match acceptable business practices, which goes to SMD
16 and FERC's function, but you could do anything, and you
17 could even in this, create models that go still secure,
18 cyber-wise, but you could do anything electronically.

19 There's lots of technologies out there that would
20 allow you to do things. If you have the components and the
21 open standards defined, you can do anything. Enough said.

22 Excellent access to information, I said that, and
23 the other part that's really good about the plug-and-play is
24 suddenly the vendors can play on a lot more equal footing,
25 and you'll see more competition and the ability of vendors

1 to compete better with each other, which I think has high
2 value.

3 So, I know you're tired of listening to me, but
4 just two more slides. Go the picture that says Development
5 Business Model. And it sounds like the words are wrong; but
6 they're right.

7 So this is where it's a little different and I
8 want to spend a second on this model, because the problem is
9 that several good efforts have gone on -- and they were good
10 efforts.

11 There is TMS and there have been other things
12 where people have worked on ideas for transaction systems.
13 One thing that was a problem was that the market design
14 wasn't the same, so it was really, really hard to do this.

15 And a lot of them were IT solutions. What we
16 really need is something that fits the market and goes in
17 there. So, several vendors and people from ISOs and others
18 have been sitting down and working through this, and so the
19 model we've been proposing is really to say that there are
20 standards groups and there are regulators groups and it's
21 not a slam to put them at the bottom of the sheet; it just
22 worked better for the thing.

23 But you notice they are not part of this -- yeah,
24 okay -- it's not part of this box up top here. You need
25 regulators. You've got to set the SMD stuff, and you really

1 need standards groups, NAESB is really important, and groups
2 like ESC and OSC, you know, the Electronics Scheduling
3 Cooperative and the OASIS -- whatever OSC stands for, OASIS
4 Standards Group.

5 Those are really important, but our premise of
6 this diagram is they're probably not the right people to
7 develop systems, and develop the open access standards.
8 They should be the ones making sure they fit, making sure
9 they're effective, and making sure they're objective, you
10 know, that they are fair and right. So you need a standards
11 group that approves what's done.

12 The thought we had was what you really need to do
13 is develop a consortium that's designed with intrinsic
14 drivers for success, which means a number of things. One is
15 that we'll have some source of revenue for paying for itself
16 and things like that.

17 So the thought we thought -- and it's consistent
18 with some things I heard this morning, was that the people
19 that know the systems the best, and that know what's going
20 on are watching the customers, and watching what FERC's
21 doing, the standards and the regulations, are the vendors.

22 And there's a bunch of them out there, and there
23 are a bunch of them that compete. So the thought of this
24 model is, and that's why there's this oval that says
25 Vendors, and they're sitting between those boxes, is each of

1 those vendors have proprietary applications, and they
2 should.

3 And those are black boxes, to some degree, right?
4 Given a function, they can do it any way they want. But
5 there's also all the hooks into those boxes, right? There's
6 a whole bunch of variables that come in and out of it, to do
7 its function inside the box.

8 And the thought was, they are the best equipped,
9 given some other members that would also be part of it, like
10 people maybe from the ESC, some of the key ISO members, FERC
11 person, maybe, but sitting in.

12 They would be the best ones to sit down and say
13 given these boxes we know about and all the hooks we need to
14 apply SMD, here's the standard, and sit down and put it
15 down. And it's very difficult. This is a lot of stuff, and
16 it's a lot of variables and a lot of things to get a handle
17 on.

18 So the thought was, why don't we propose -- I'm
19 applying it to the West right now -- why don't we propose
20 something that's aimed at being successful at developing
21 open systems and open standards.

22 Let's put the people that are most knowledgeable
23 at it. I've heard Alstrom suggested, and maybe one of the
24 models is to have them self-provide their labor into it, and
25 there also probably would have to be some things you pay

1 for, like process management and some audit people, right,
2 to kind of watch and project-manage what's going on, and
3 have them develop and implement open standards and
4 supporting systems.

5 And by supporting systems, on that other sheet,
6 there was something that said a data mart and a validation
7 thing. There is someplace where data has to know where it's
8 talking, and you store data. You have storefronts so you
9 can get the data you need to make the whole thing function.

10 And certainly have it highly, highly interfacing
11 with the traders, the RTOs, ISOs, and the generators and the
12 load-servers. And let them take the shot at it, and then it
13 would be standards that would have to be approved by the
14 appropriate standards groups.

15 That's the part that I think is a little
16 different, and we don't frankly care what model is used.
17 I'm almost done. But we think that something like that
18 needs to be done that could be successful.

19 So I think I don't really need to talk about what
20 FERC could do, except just to say support the flexibility to
21 allow implementation of such things as that, support
22 developing a comprehensive western interface like that, and
23 support stakeholders. We really need to do that, because I
24 think it will take FERC's support of something like this to
25 say we believe this is the right track, go do it.

1 And finally, I think this is a significant step
2 toward a single market vision and a big one. And however we
3 do that.

4 (Fire alarm sounds.)

5 MR. WATKINS: I'm done.

6 MS. SILVERSTEIN: Let's pretend that it's a real,
7 live fire alarm.

8 (Recess.)

1 MS. SILVERSTEIN: What we're going to do -- now
2 don't make me do this to you again -- what we're going to do
3 is continue with Mr. Thompson, and then we're going to go up
4 and down the row asking questions of all of you, and overall
5 unless anyone objects I think we'll just pretend that we
6 took our 15 minute break. We're going to keep this panel
7 going to 3:30 and then rather than do a 15-minute break
8 then, if you need to get up and use the facilities, please
9 do so, but let's just keep going and switch panelists or
10 bring up the next batch because as I recall you all are just
11 sitting tight in those chairs. What that'll do is in fact
12 expedite the schedule a little bit. I know some of you need
13 to run for airports and all so if we're lucky, this might
14 let us wrap up 15 minutes earlier. Again, however, do not
15 be shy. If you are a panelist and you're up here to be part
16 of a conversation, and it's time for you to go catch a cab
17 for the airport, wave goodbye and take off.

18 In anticipation of that, thank you all so much
19 for coming today and for being part of this. I think we're
20 all learning a lot on this side of the table and I hope that
21 you all are as well.

22 Mr. Thompson?

23 MR. THOMPSON: Thank you, Alison. My name is Bob
24 Thompson from the New York ISO market and systems design
25 consultant, and was previously the project manager for

1 implementation of the existing ISO software systems. And
2 I'm going to address several issues. I have a presentation,
3 copies of which were available in the back. We'll be
4 discussing lessons learned, what we now know about software
5 implementation and ISO operations that we didn't know when
6 we put this system into operation in November of '99. And
7 the areas that I'm going to talk about briefly here are data
8 requirements which have been discussed at some length. I'll
9 talk about a couple of other aspects of that.

10 Testing, scheduling, and particularly scheduling
11 software. Software itself, and last some seams issues and
12 some perspective on seams resolution.

13 What we've seen as the -- we were pretty clear
14 about what the data requirements and the posting and
15 scheduling requirements were associated with running the
16 markets normally. Before we began what we did not realize
17 was the I think the degree to which sort of what Andy was
18 referring to their PJM's focus on market participant data
19 needs and the information that market participants need in
20 order to understand what the market's doing and why things
21 are happening the way they're happening.

22 And we have been in a fairly continuous mode of
23 catch-up in that arena from the beginning. And the other
24 major area that has been growing and continues to grow is
25 the requirements of market monitoring, and specifically the

1 ability to get at the information that is the kind of
2 information that market monitoring needs to do their job.
3 And my sense is that with FERC now focusing, having their
4 own market monitoring group, that that requirement is not
5 going to be reduced, it's going to be growing. And both of
6 those are significant considerations in software design.

7 Also one other item that Dave La Plante talked
8 about billing systems. We also have a homegrown billing
9 system in New York. It has been under constant change and
10 modification as we've made market changes and we've
11 corrected market problems. All of that stuff filters down
12 to the billing software. It's continually being modified.
13 And one of the other aspects of that is that the
14 information, a lot of the information coming into the
15 billing system really comes in through the next tier at New
16 York which is the transmission owners and the existing
17 metering system that the markets were sat down on top of.
18 We've spent an enormous amount of time resolving data issues
19 associated with billing, and the consequent rebilling and
20 trueup processes that we've been involved in.

21 One of the things that we may want to look at in
22 looking at standards is what is the reasonable amount of
23 time to allow the market to establish final prices before
24 they are fixed permanently and are not going to be revisited
25 again because someone found some metering errors within the

1 system two years ago.

2 Moving on to testing. New York, as most of you
3 probably know, we started into this business differently
4 than did PJM and New England. We did the big bang approach
5 where we went from nothing, from no markets to day ahead and
6 real time and ancillary service markets, all in one stroke.
7 And have been continuously in a process of change since that
8 time. One of the investments that we've had to make that
9 turns out to be more of an issue than we thought it was
10 going to be is in an adequate bid to build quality assurance
11 system where, as we make changes, and modifications to the
12 way in which the system works, we can have confidence when
13 we actually take those changes to the production system that
14 we have sorted out any bugs or problems that may be present
15 there or in the new function or the modified function as
16 well as de facto we haven't broken anything else in the
17 system.

18 We are not completely successful at that, but as
19 you go forward, I think when you're not successful at that,
20 you end up with billing issues, and you end up with a whole
21 host of problems, and the presence within the systems and
22 the software suite of an RTO or an ISO really must include a
23 very adequate and well designed testing and QA facility, and
24 it's not cheap. One of the aspects of that that has not
25 been discussed here much is the area of simulation. The

1 simulators that most of us have available to begin with are
2 simulators used for dispatcher training. And I think that
3 some additional work needs to be done in looking at what
4 should be done to the simulator facilities that may be part
5 of your QA system that would give you the ability to
6 adequately address the market conditions and the system
7 conditions that the new software or even in the case of
8 areas where you're looking at potential changes and you want
9 to determine what the effect might be using a simulation
10 facility to be able to identify that.

11 Now the next subject that I'll talk about briefly
12 is scheduling and I think here I'm going to -- I want to add
13 to the discussion this morning on the adequacy of the
14 current technologies in the area of scheduling and network
15 based applications, particularly unit commitment and unit
16 commitment based functions like day-ahead market and in New
17 York the real time dispatch.

18 I don't actually disagree with any of the numbers
19 that were discussed this morning, but what is true is that
20 there are issues other than simply scale. And they're
21 really complexity. If you take John's comments on the
22 testing that we've done on the expanded model for the
23 Northeast RTO in New York, and he talked about a linear kind
24 of three times expansion in terms of execution time. That's
25 accurate. But what's not obvious is that if you then look

1 at the consequences of, say, a more sophisticated mitigation
2 philosophy that requires you to go through that process more
3 than once, go through it one time to determine whether or
4 not you have a circumstance in which mitigation is required
5 and having applied mitigation, do you now have to go through
6 the process a second time in order to determine what is now
7 the correct commitment or the correct commitment and
8 dispatch.

9 And then you have a three times expansion due to
10 scale and a two times expansion due to functionality, which
11 gives you overall a sixth time. The mitigation is one arena
12 in which we see additional functionality being added and
13 demands made -- Yes?

14 MR. O'NEILL: Would you do a full model pass in
15 the mitigation procedure?

16 MR. THOMPSON: Yes. Yes, we do.

17 MR. O'NEILL: And why do you think that's
18 important?

19 MR. THOMPSON: It depends on whether we're
20 talking here about the day-ahead commitment or real time.
21 In the day-ahead unit commitment, we actually have, we
22 actually go through the process a number of times, and for
23 mitigation purposes, we only go through a portion of it.
24 But in real time, away go through that very same portion
25 once, and then we come, and if mitigation is called for, we

1 mitigate and then come back through it again, and while it's
2 a shorter period of time, the execution time for the real
3 time commitment and scheduling process is short compared to
4 day-ahead, but you also have a very short time to do it in.
5 We're talking now about 15-minute scheduling intervals and
6 five-minute dispatches, and you must be able to accommodate
7 those things that require you to go through your
8 optimization software as many times as are necessary to
9 handle the functional requirements. Mitigation is one. A
10 second one in New York, and it may not be the same
11 everywhere, but is our management of the gas turbines New
12 York City. Can that process and establishing the correct
13 signals for the pricing solution require us to also go
14 through many portions of our real time dispatch software
15 more than one time.

16 So my point here is that we are not just dealing
17 with issues of scale but we're dealing with issues of
18 increased functionality when we look at the performance of
19 these applications. And that is you get into demand side
20 response. We may have more, and I don't think we can rest
21 comfortably with the fact that our particularly in the area
22 of the commitment and the optimization software, that that
23 technology which is based on some fairly old methodologies
24 doesn't need to be looked at as a candidate for significant
25 improvement in performance.

1 Relative to software, a little bit of just
2 motherhood here, the software design in general. I think
3 the componentized software design open architecture,
4 standard interfaces we've talked about. One of the other
5 elements though is the incorporation in the basic
6 infrastructure of technologies such as the Enterprise
7 architecture integration methodologies, which are going to
8 significantly I think improve the ability to make changes in
9 a more timely manner, to improve the performance in testing
10 of software which tends to be one of the real time-consuming
11 efforts.

12 Our time is spent in design and in testing. The
13 implementation of changes is relatively straightforward and
14 does not take a great deal of time. Coding is not a long
15 time-consuming process. It's really making sure that before
16 you ever start coding, you've actually gone through and
17 looked at all of the aspects of your operation that are
18 affected by some potential change, and that you know
19 everything that you're going to have to do.

20 And then in the end when you've got the software
21 back, and it's been through modular testing, is the system
22 level testing and developing confidence that this thing
23 works in a whole variety of circumstances before you stick
24 it into the system. And I think the EAIR architectures are
25 going to be very helpful in that process also, and being

1 able to integrate test facilities in with your overall
2 system architecture. And the presentation actually has a
3 diagram of one of those architectures in it, so you can just
4 for reference here.

5 Lastly, I'd like to talk briefly about seams. I
6 think I would agree with the general thrust of things here
7 which seems to be that focusing on the market participants
8 issues and problems associated with scheduling and
9 interfacing with various ISOs for the scheduling of their
10 transaction and their energy is a good way to approach it.
11 To look at it from the user's point of view and that the
12 efforts in the Southwest as well as in the Northeast here
13 towards developing some standard or some one-stop-shop
14 interfaces for the various ISOs and RTOs that exist in the
15 region can be a mechanism to force that to happen.

16 I also think that if FERC focuses a great deal of
17 attention on that and holds people's feet to the fire in
18 terms of timing and getting that accomplished, it would be
19 very helpful because it helps establish the priorities in
20 which software development is scheduled at these various
21 locations when that's present, that kind of emphasis.

22 MS. SILVERSTEIN: By locations, do you mean in
23 the vendor's house or in yours?

24 MR. THOMPSON: No, I'm talking about in the ISO's
25 house. People who are writing the checks for this stuff.

1 And then also I think related to seams, I'd like
2 to talk about one other issue and that is that it's that
3 software rules, changes, standardization of rules, and
4 software alone, are probably not going to be an adequate
5 solution for seams issues. There's a lot of what's involved
6 in solving seams issues that has simply to do with the
7 control areas communicating with one another and cooperating
8 with one another. And that's where I think that the
9 influence of the regulators can have some real impact is to
10 help get both the management as well as the technical teams
11 in the multiple control areas focused on actually solving
12 the problem. When they do that they can solve them pretty
13 quickly.

14 When they are guarding other projects and working
15 off of other priority lists it can be easy to postpone and
16 move out efforts that would facilitate this kind of process
17 change because it involves changing on the operations floor,
18 it involves some changes in the IT organization, software
19 plans, etc., and the kind of emphasis that FERC can bring to
20 bear in this area saying you must get this done can help
21 make that happen.

22 But I think that a lot of what needs to go on is
23 a matter of communication and cooperation and not so much of
24 a lot of software changes. Just as a sidelight, the idea
25 that having the same software will somehow eliminate a seam

1 was kind of just proven last week or so between the IMO and
2 New York who have nearly identical real time scheduling
3 software. And yet it was our process, an incomplete process
4 that we'd been working out with them, that was the source of
5 failure and created some scheduling anomalies where we were
6 not in fact scheduling transactions that we should have
7 been, and it had nothing to do with dissimilarity in
8 software. We schedule with entities that have dissimilar
9 software and even objectives on a regular basis and with
10 processes and procedures that work. There is not a
11 necessity to make all of the software in an area identical
12 in order to solve these kinds of seams issues.

13 So just in summary, I think that as far as
14 software and system infrastructure, I think we've got to
15 focus more attention on incorporating modern tools and
16 technologies and particularly I think that in the area of
17 scheduling software, that's going to become more critical to
18 us, and as far as seams resolution, I think SMD is going to
19 help and FERC's focus is going to help. But that we need
20 to really begin working much more cooperatively together to
21 get these solutions implemented.

22 MS. SILVERSTEIN: Let me follow up by asking you
23 first and then inviting everyone else to jump in, the
24 following question. And it goes to your point about the
25 safe software won't make the seam go away. That my

1 impression of what you said was that it's more about human
2 communications and scheduling issues and practices that get
3 in the way rather than the software. Let me follow that up
4 by asking then if we're always going to have problems with
5 those pesky humans and their communications and practices
6 issues, will having the same software make it easier to work
7 around the humans.

8 MR. THOMPSON: Well, I don't think it's just the
9 presence of humans. It has much more to do with the
10 business processes. If you look at two control areas,
11 whoever they are, control areas A and B, with identical
12 software, but each of them solving their own internal
13 network and business problems, and there's a set of ten or
14 12 transactions that are candidates to go between those two
15 control areas. And if they go about their scheduling
16 process independent of one another, and then come together
17 as they do today, 30 minutes before the hour, and control
18 area A tells control area B well, I've got the following
19 transactions scheduled. And control area B looks at his
20 list and includes a few of those but not all of them.

21 And what they settle on are those that they have
22 in common. It can be a process that's as simple as the
23 protocol that we developed with the IMO is that actually the
24 IMO closes their hourly market ahead of us and looking at
25 the set of transactions that are candidates to go between

1 control areas, we do not include in our evaluation any
2 transactions that have not been scheduled at the IMO because
3 they're going to get cut anyway. They're going to get cut
4 in the checkout process. They're not going to flow simply
5 because we schedule them. They have to be scheduled at both
6 ends.

7 MS. SILVERSTEIN: Just to be clear, one of the
8 things that we want to do in SMD is we will eliminate a lot
9 of those disparate scheduling processes for instance. We
10 will not do it in the rule but we will say you will use, for
11 instance, the same point of time on the clock to define your
12 starting hour, or you will do your scheduling and you will
13 all close it at the following minute, or you will all do
14 ten-minute or 15-minute, although the details of that are
15 likely to be worked out at NASB, once we make the policy
16 call.

17 But my underlying question to you is
18 notwithstanding the fact that we can't standardize humans,
19 nonetheless will having common software make it easier to
20 deal with the non-standard human problem.

21 MR. THOMPSON: I actually don't know that it
22 will. I don't know that it will. It could. I think for
23 instance closing at the same time is probably may not be the
24 best idea. A cascaded close is far easier for people. I
25 know that people in New York, because away post our

1 schedules, our day-ahead schedules at 11:00 o'clock, go to
2 New York, determine what's been scheduled in New York, and
3 then make adjustments in neighboring control areas, and I
4 think that that's a useful thing.

5 MR. LA PLANTE: In terms of the seams for
6 transactions, there's sort of three causes. One is software
7 limitations. I know New York runs BME and it takes them 75
8 minutes to get the data in and run the BME and make a
9 decision about it, so that's a software limitation. It may
10 be able to be fixed. So everyone having the same software
11 that was efficient could fix that.

12 There's also business process and checkout things
13 which I think you were just discussing where you just need
14 to streamline that and people can get efficient about doing
15 it at the same time and in the same way.

16
17
18
19
20
21
22
23
24
25

1 That is something that could be worked on and
2 improved. I think SMD may help do that, but I think people
3 working together can help do it, too, and I think we have
4 done a good job of that over the past couple of years.

5 Since New York's market has gone into effect and
6 since we've all put markets in, we have all improved our
7 process as a checkout, and I think it has improved things.
8 So those areas can be improved.

9 I think the final area where the seams are going
10 to continue to exist until we have central dispatch is that
11 the price to sell out of one area is going to be different
12 than the price to sell in from the other area.

13 You really can't do anything about that if you
14 have two control areas and two markets, as the price is
15 based on what's going on in the individual market.

16 So that is sort of the limit that we can go to.
17 We can't solve that problem without changing the market
18 definition.

19 MS. SILVERSTEIN: Andy, did you want to talk
20 about this?

21 MR. OTT: No.

22 MR. PALIZA: I think having standard processes in
23 place will help in managing the seams, but there are some
24 issues, some seam issues, that go beyond the standard
25 processes in these markets. I will just put one on the

1 table.

2 How do you honor external flow gate?

3 How do you compensate for loop flows caused by
4 external systems?

5 So we shouldn't do the prospective of, you know,
6 some big issues that impacts some regions in different ways.
7 This is just as important for Control Area A, but maybe not
8 that important for Control Area B. It depends on the
9 configuration of the system and how much they are
10 intertwined with each other.

11 MS. SILVERSTEIN: You are absolutely correct.
12 And of course one of our goals in Standard Market Design is
13 to handle the easy seams issues so you guys have more energy
14 to deal with the hard ones.

15 MR. PALIZA: Thank you.

16 MR. LA PLANTE: We're getting bored.

17 (Laughter.)

18 MS. SILVERSTEIN: We could have another fire
19 drill, if that would help.

20 (Laughter.)

21 MS. SILVERSTEIN: Let's go back to a topic that
22 was mentioned right at the beginning, and that is education
23 and the importance of having market participants
24 understanding what it is you are doing to them and what it
25 is they have to do back, and why, and how.

1 I wonder, Cherie, since ERCOT did this pretty
2 thoroughly and it wasn't enough, can you talk about what you
3 did and what you would do differently, and what others need
4 to do?

5 MS. BROADRICK: Yes, I would love to talk about
6 that because it is near and dear to my heart.

7 In ERCOT we did what we called a series of market
8 readiness series meetings. We did those every other month.
9 We came out with presentations and invited all market
10 participants. But what it failed to do was failed to be as
11 interactive as I think we are going to have to become as we
12 continue to change and work with our market participants.

13 I noted a few things down here, so I am going to
14 kind of read from them so that I don't miss anything.

15 I think to adequately prepare market
16 participants, you must first require your vendors to engage
17 in the training of both your staff and the market
18 participant's staff.

19 So I would expand that role, if I were to do this
20 again, and I would put a lot more pot of dollars towards
21 market participant training and expectations from the
22 vendors.

23 Our vendors did a train-the-trainer approach, and
24 this was not sufficient. Training material was developed
25 too soon. So when we started up, it wasn't relevant. So

1 that 's another thing.

2 Look at where they're going to develop the
3 training material. Make sure that it is done on the back
4 side, or in increments to where it is relevant.

5 I would require vendors to publish technical
6 specifications often, often, often, and stand ready to
7 answer questions.

8 I would also encourage the development of a
9 technical implementation group very early in the process.
10 This is made up of vendor staff, ISO staff, and market
11 participant staff. Let them Storm Norm all the things that
12 groups do before they get to the weighty issues.

13 Let them become a cohesive group. Then, as you
14 are marching through implementation, they know how to work
15 together. One of the problems that we had is that we
16 weren't visible enough with our technical specifications to
17 the market participants.

18 Our CEO makes a statement that I love to hear him
19 talk about. He said: It's not the problems of where we met
20 up at the flange; we did really well at that. It's the
21 problems behind the flange.

22 You thought I meant this.

23 I thought you meant that.

24 And we're certainly not talking.

25 The flange is okay, but we're doing something

1 logically behind that flange that's not making sense.

2 This technical group--and I can't stress this one
3 enough--is hard to do. It's great to say, and it's very
4 difficult to do because of distrust issues. But you've got
5 to get this group together and make it a technical
6 implementation group. Get the right folks to the table.
7 This is not one where it is high-level business folks. It's
8 the implementation people.

9 This group should then morph into your testing
10 group, and an ongoing Q&A group for your market. I would
11 put a lot of respect into this type of group. And we're
12 still working with this in our pot. we're still trying to
13 develop that. We've not even gotten there with this piece
14 of it.

15 I would bring this up to the forefront of your
16 implementation of Standard Market Design and let it flow
17 through the whole process.

18 MS. SILVERSTEIN: Anything on training from other
19 ISOs?

20 MR. WATKINS: We've been looking at that in the
21 West. One of our ideas really between RTOs is to do joint
22 training. We want scheduling coordinators to have a similar
23 interface.

24 So the idea is: Why train them all separately?
25 Do something jointly and develop programs simulators and so

1 on to do that, as we're building it and as it is
2 appropriate, as she mentioned.

3 MR. THOMPSON: One other comment. It is not
4 specifically training people; it's more a matter of allowing
5 market participants to get their systems prepared.

6 These guys all have systems out there as well,
7 and they're faced with ours, and getting a thorough, full
8 understanding of exactly what the electronic interfaces look
9 like, how they work, good protocol definitions, et cetera,
10 is immensely helpful, as well as an opportunity to test them
11 out.

12 MR. LA PLANTE: One small note. There can be too
13 much emphasis on interfaces, on the actual interfaces,
14 because most of the data that gets submitted is submitted by
15 file uploads by large companies.

16 So while there may be some interfaces that are
17 used heavily maybe operator-to-operator, a lot of the
18 commercial work is really done using file uploads.

19 So in terms of designing and thinking about
20 things, you don't want to spend--interfaces can be
21 expensive. So if you put all your emphasis there, you could
22 end up spending lots of money on interfaces that really
23 aren't used.

24 That's just something to think about as we move
25 forward.

1 MS. SILVERSTEIN: Changing the topic slightly,
2 FERC has, in the year I've been here, a fair amount of
3 experience at saying: ISO go change your system to do this.
4 And getting a little bit of push-back from ya'll about the
5 feasibility of making software do the thing that we needed
6 to do--and I heard a little bit of that in your discussion.
7 Jamie Sample, talk to him about how to make AMP work,
8 please.

9 And beyond that, more broadly I've heard you all
10 essentially telling the vendors what you need them to be
11 doing and thinking differently. For instance, updating the
12 technology and algorithms inside the State Estimator box and
13 the Unit Commitment box.

14 To what degree is there--and, vendors, I'm going
15 to ask them first, and then ya'll will be back up at the
16 table and you can have a rebuttal opportunity--to what
17 degree do you have these discussions directly with vendors
18 about here's what it is we need, and here's how it needs to
19 change, and here is how important it is or isn't to us, and
20 what the deadline needs to be.

21 MR. THOMPSON: We work pretty closely with
22 vendors on software development. We generally bring them in
23 early, and I'm thinking now about our continuing effort at
24 changes and modifications, as opposed to an arm's length
25 where we write a specification and throw it over the fence.

1 It's not that kind of an arrangement at all. We work quite
2 closely with the vendor almost as a team to implement these
3 changes.

4 Many of them are new, and the risks of getting
5 them wrong are high. And so we share those risks.

6 MR. LA PLANTE: It's not so much getting them in;
7 it's the time it takes to do it. We work well internally.
8 We've been working on these markets for three years. We've
9 gotten relationships with the vendors. We've improved our
10 internal processes quite a bit.

11 We've improved the way we work with the market
12 participants to do these things. But I think Bob made an
13 excellent point earlier. The time comes not in the coding
14 of it but really in the design and the testing of it.

15 They are complex systems, so when we get a
16 request to do something in a short period of time, it just
17 may not be consistent with good software development
18 practice to get it done within that time.

19 So it's just a lot of work.

20 MR. OTT: I think one area is obviously a
21 cooperative relationship with vendors. You have to do it if
22 you're going to keep the pace of this. I mean the changes
23 we're making to large systems are as fast as we are.

24 But I think the other thing you have to work with
25 with your vendor is the training issue. We actually train

1 the vendors, because they have to understand your market and
2 what the implications are. Because when their people are
3 doing the work, the more they know about the way you use the
4 stuff the better.

5 We actually invite vendors to sit on our floors
6 to actually see how the stuff is used to make it better. I
7 think that is probably part of the cooperative relationship
8 you're talking about.

9 I think that kind of interaction has to happen
10 and does happen.

11 I think the biggest issue with, as you're talking
12 about the pace of change, if you will, is really managing
13 change, how should I say, and still making it audible and
14 still making quality happen.

15 Essentially you can't just throw a change in and
16 close your eyes and hope. So I mean that's really been the
17 biggest issue.

18 MS. SILVERSTEIN: You have been the setup man for
19 my last question for this panel. Which is, the change
20 management process.

21 We learned in Texas when we were doing telecom
22 competition and creating a wholesale telecom competition and
23 retail competition there, that he who controlled the legacy
24 systems wins. And, that you could use back-office systems
25 essentially as a barrier to entry or as a way to delay

1 competition if you were an incumbent, and the only way we
2 could make systems change over time to evolve into something
3 that could support a competitive market was that we needed a
4 rigorous change in the management process that had
5 participation by the customers as well as the vendors, and
6 so on and so forth.

7 Everything was rigorously documented and
8 explained and rolled out and justified and managed, and so
9 on and so forth, so that everybody got there at the same
10 time. But in telecom, that was, I'm going to say,
11 relatively easy. I know you are all going to roll your
12 eyes. In comparison to this, largely because there is one
13 incumbent and we know the software for that stuff works, and
14 there were not so many competitors that you couldn't fit
15 them all in a room and roll it out in a coordinated fashion
16 if you could get them to agree technically what needed to be
17 done.

18 Yet here, we are looking at a significantly more
19 complex set of software with a significantly more complex
20 set of users and needs.

21 So have ya'll given any thought to going forward
22 under something like Standard Market Design? How do we make
23 a change management process work so that it doesn't create
24 more chaos than it causes and we don't get stuck with
25 electric market software that looks like what the FAA is

1 using to land airplanes?

2 MR. WATKINS: I've got one thought on that. And
3 again we haven't built anything, but we've had a lot of
4 discussions with California, and we have had an open forum.
5 We had the vendors present, and others, and a lot of those
6 vendors have been involved with you guys.

7 And the thought was, and especially Washington
8 and California, is if you push too fast, you end up with
9 poor change management. You don't get what you want.

10 They often had systems that got built before the
11 requirements had been sealed, where people didn't understand
12 the pieces. So there is somehow this fine line between
13 pushing hard for diligent action and going so fast that you
14 miss.

15 MS. SILVERSTEIN: So you're talking case
16 management?

17 MR. WATKINS: Well, and I'm assuming when you
18 say--we have change management that says if you change
19 software you have to write it down, and all that, and I
20 assume what you're talking about is managing the culture so
21 people change, so you bring implementation of change?
22 Right? Is that what you're talking about?

23 MS. SILVERSTEIN: (Nods in the affirmative.)

24 MR. WATKINS: Yes. And so one of the problems
25 is, if you--I am going to be bold here--if you come out and

1 say you have to do this, and we want it in a year, and you
2 didn't do this, California, but their state law did, it had
3 to be done very quickly, what you will do is not be able to
4 manage all the pieces you need to in getting people ready
5 and moving people up to speed.

6 MR. OTT: I think as you are managing these
7 things, again, you can intelligently manage change. In
8 other words, if for instance in a market we're rolling out,
9 obviously we understand the important changes we need to get
10 out there to sort of get notice out, or lock down very
11 quickly, is the User Interface Change.

12 In other words, you've got to tell the users
13 eight months ahead of time, or whatever it is. In other
14 words, our spinning reserves market going in in the fall,
15 the protocols and data transfers were designed and sent to
16 them so they know what to expect.

17 You know, that was locked down early. Where
18 there are other things you can, in the change management
19 process, you can allow the change as you move forward and
20 learn more as you actually implement.

21 So I think there are ways. I mean this isn't
22 like--it sounded a little gloomy, so I figured I would throw
23 in something positive. I mean it isn't necessarily an
24 impossible task to intelligently manage change.

25 I think the issue of change management is you

1 need a plan. You need a way to do it. You need
2 coordination to do it.

3 I think when I say "you" I mean the RTO and its
4 participants, or its stakeholders, if you will.

5

18

19

20

21

22

23

24

25

1 Obviously the RTOs are each other's stakeholders
2 to some extent because we share data with each other. But
3 to be honest, the vast majority of the impact is on our own,
4 the people who are participating in the market and of course
5 our own employees.

6 But I think you can do it in such a way that you
7 lock down the necessary things early such that the affected
8 parties have a chance to manage their own change, if you
9 will. So it's not necessarily an impossible task.

10 MR. LA PLANTE: Were you speaking of the change
11 of rolling out a market in an area that wouldn't have a
12 market? Is that sort of change management?

13 MS. SILVERSTEIN: That's part of it too, but I
14 was thinking more specifically about -- that's big changes.
15 I was thinking about procedural changes like we're going to
16 migrate from version five to version six or we're going to
17 throw in this new set of bells and whistles that change the
18 way we do the following thing, which is the kind of change
19 that you all do more frequently I assume.

20 MR. LA PLANTE: Right. We have gotten better at
21 that I think as we've done more and more of them. We've
22 heard from our participants what we haven't done well, and
23 they've helped us do it better.

24 MR. OTT: And I think that's kind of our message
25 too. Our market participants trained us fairly early, and

1 we've evolved a process in which market participants are
2 very involved at the front end actually in helping define
3 requirements and design functionally how these things are
4 all going to work.

5 And we've developed a process of fairly close
6 communication through the committees of presentations well
7 in advance in a series of them coming up, so that
8 particularly for anything major, there is a coordination
9 with the training program as well as a lot of presentations
10 so that people who would possibly not be getting the word,
11 people who are going to do the billing processing and the
12 folks that catch the tail end of these things are well aware
13 ahead of time and people have an opportunity to adjust.

14 MS. SILVERSTEIN: At this point we're going go
15 bring back up the folks from the vendors and Clark Kellings
16 of EPRI and while you all are coming up, Marv and Phil, do
17 you all want to move down a little closer so we've got room
18 for them at that end? And I want to offer you an opening
19 question to think about while people are moving around.
20 Don't have to wear jackets for this. It's summertime in
21 Washington, so lose the jackets.

22 The opening question that I offer you is, we were
23 talking about the necessity of specs and about managing
24 expectations for each other and educating market
25 participants, and so my opening question for you all to

1 think about is, does a draft Standard Market Design proposal
2 with warning that the final is coming out in December and
3 opportunities to comment and shape what those look like in
4 technical workshops along the way constitute appropriate
5 notice and expectation management for the process of
6 developing expectations about what the next generation of
7 software needs to do and look like?

8 (Pause.)

9 MR. WATKINS: Could you repeat that? We were all
10 watching each other.

11 (Laughter.)

12 MR. WATKINS: Sorry, Alison. It was a very good
13 question I'm sure.

14 (Pause.)

15 MS. SILVERSTEIN: Okay. Is this everybody? I
16 think the question that I just asked was, we were talking
17 about the importance of everybody understanding what's
18 coming and what the requirements are and what you need the
19 software to do and working with your vendors to say this is
20 what it needs to do and working with your customers to make
21 sure they understand what's coming at them. And my question
22 for you is, does a NOPR issued in July with the opportunity
23 to comment and the opportunity to participate in technical
24 workshops to shape pieces of that and make sure everybody
25 has a common understand of what's in it, and then a final

1 rule developed based on those comments and that proposal in
2 December, how does that do in terms of educating you and
3 your vendors and your users as to what's coming down the
4 pike?

5 The format for this portion of our program is, if
6 you've got something to say, wave or raise your hand or leap
7 for the mike.

8 MR. OTT: I think the format works fine if when
9 the ruling comes out there is appropriate length of time to
10 comply, if you will. I think having the forum to put out a
11 NOPR, have I guess meetings and comments to further
12 understanding, et cetera, and then having a final ruling, as
13 long as the filing ruling then gives some additional time
14 for all of us to comply if you will, that's probably fine.

15 MR. PALIZA: In addition to that, I would say
16 that a key aspect of the success in implementing the
17 Standard Market Design is in how much detail you are going
18 to include in that NOPR. Are we expecting, I mean, all the
19 way down to the market rules? Are we expecting a high level
20 type of NOPR? That's a key aspect of it, because whatever
21 is left, you know, is something that the vendors and the
22 RTOs will need to complete. How much work is left for us to
23 do?

24 And then as Andy mentioned, it is important a
25 timeline. Is this something that we have to be doing in

1 stages? Is there flexibility in the implementation process?

2 MR. O'NEILL: I would expect that part of your
3 comments in response to the NOPR will address issues that
4 you wish to educate us on, like what you think the
5 appropriate pace and sequence and timing of the
6 implementation of SMD should be.

7 You need to help us understand what it's going to
8 take to make this work and what needs to be rolled out
9 first, and I also expect that your comments will tell us
10 whether we've hit a level of detail that you can start
11 writing software to or whether we need to go higher or
12 deeper in order to give you something that gets us models
13 that do the same thing every time in every part of the
14 country, which is our goal.

15 Anyone else?

16 MS. BROADRICK: I was going to mention, it
17 doesn't seem to me that we look at phasing things as often
18 as we should. And that's something that I think is a very
19 appropriate way to make these large-scale changes in a
20 market is phasing them.

21 What that buys you is an ability after that you
22 hit that phase target to look around and say okay, let's
23 give ourselves another month and see how are we doing with
24 what we just implemented.

25 So it gives you the ability to take a pulse and

1 say, do we now go forward to phase two, instead of just a
2 big bang theory that most of us have experienced.

3 And the problem with the big bang theory is
4 sometimes there's so many things wrong you can't even find
5 which ones are really causing a problem. You're treating
6 too many symptoms.

7 So I would encourage the markets as we continue
8 to grow to start looking at phasing things and digest them
9 when we get to those phases. Let's really see so we can
10 identify what the problem is and not just treat the
11 symptoms.

12 MR. BRITTON: One comment I'd like to make is
13 Standard Market Design does not necessarily imply standard
14 software design, and I think those two things a lot of times
15 get mushed together.

16 What will be interesting is in the NOPR the
17 extent to which it dictates elements of standard software
18 design, and I would hope that there are bits of it that are
19 doable and most of it is left to us to implement. That will
20 be the most effective way to do it. But that's just a big
21 open issue that we don't have visibility into yet.

22 MR. GELLINGS: Alison? I agree with Jay's point,
23 but there is a piece that was covered rather well this
24 morning that may be worth circling back to for just a
25 moment, and that is the question about market data

1 interfaces. Not the modeling, not the how the computation
2 is done, but what the data set looks like.

3 And I think an important part of Standard Market
4 Design ought to be suggesting that that be standardized,
5 essentially standardizing the ability to then communicate
6 data. I think the point was made strongly this morning by
7 others that that reduces costs and actually promotes
8 competition and encourages innovation as long as of course
9 you stay away from the model design issue.

10 Of course, you do break down some proprietary
11 barriers. We heard a couple of very large vendors indicate
12 that that's actually a good thing. And what we're proposing
13 to do is to extend -- and the suggestion has been made by
14 several others -- the EPRI common information model to the
15 market side. It's already quite well used on the operations
16 side. NERC now requires regional security coordinators to
17 exchange system modeling information using CIM-compliant
18 databases.

19 We're currently applying it on the planning side,
20 developing applications there, and announced, as you may
21 know that on September 12th we're going to hold a workshop
22 specifically about CIM extensions and provide an open forum
23 to discuss how that might be done.

24 MR. IRISARRI: I was just going to mention that
25 my expectation of the NOPR is that it will be perhaps an

1 unambiguous requirements definition document that we can
2 interpret more or less in the same terms, all the vendors,
3 so that we can develop our applications to meet those
4 requirements rather than going ahead and start implementing
5 something that then later we are told sorry, but this is not
6 what we as an RTO understood that process to be or that
7 process to mean.

8 So that requires some level of detail and some
9 tightening of definitions and concepts so that it can be
10 interpreted in a clear manner by all the interested parties.

11 MS. SILVERSTEIN: I think that is our goal as
12 well. The question is whether we can deliver that to you.
13 But we're working pretty hard at it.

14 MR. BRITTON: I have one comment to what Clark
15 just said on the common information model. And I think he's
16 raised an issue that actually is a good illustration of the
17 point I stated earlier more generally.

18 I want say two things. One is I think the Common
19 Information Model is a very good thing as engineering
20 effort, and it's an excellent idea to extend it into
21 markets. I think it would be a terrible idea to specify it
22 in a NOPR.

23 And the reason is that there's too much left to
24 do, and that's precisely the kind of thing that would delay
25 the process quite a bit.

1 So I'll leave it at that. I won't try to go into
2 more detail as to why.

3 MR. O'NEILL: I guess one of the questions and
4 one of the issues that I hadn't fully understood or fully
5 taken into account was the impact on participants.

6 Each market participant probably operates in each
7 one of the ISO or RTO markets and has its own processing
8 software. So there's a lot of additional benefit to
9 standardizing the data. And I was wondering, I mean, Clark
10 has obviously put down a modeling proposal or a data
11 proposal, and Jay is not terribly excited about it. And
12 we've introduced new terms here. We have standards,
13 guidelines and open data.

14 And could we just get an idea of whether or not
15 -- by the way, I don't think the NOPR will standardize the
16 data. The question is whether the NOPR asks the industry to
17 standardize the data. And by "the data", I mean the input
18 and the output of these models.

19 And also, after talking to some people, I don't
20 mean the processing to get it into a data structure that's
21 efficient for processing the algorithm. I mean something
22 that's reasonably standard in terms of, for example, Andy
23 being able to interchange data with Dave or Roberto and not
24 have to reconvert the data and not have to send his
25 engineers into the database to figure out what happens.

1 Could you guys talk to that? Whether or not at
2 what level of standardization or whether it should happen?
3 Andy?

4 MR. OTT: I can certainly talk about whether it
5 should happen. I think I would throw in I think it has to
6 happen. And again, I think obviously Dave, I and Roberto
7 have to share data with each other.

8 In fact, when PJM West was implemented, one of
9 the largest challenges again we had to bringing that in was
10 getting the real time data model in and getting it to work.
11 Again, it was the biggest single effort that we had to do.
12 So those kinds of things, again, as you bring models
13 together.

14 But I think the other thing we're missing is
15 again when I try to give my data model to my participants
16 so that they can take the same model I have, use the six-
17 month-old data that I post and do analysis to get confident,
18 or that they understand what's going on. I mean, it's very
19 difficult for me to give them the data because, again, in
20 the type of structure, the breaker format type, it's really
21 difficult, and that's the whole CIM issue, right?

22 But I think beyond that then you go into the
23 market model itself. And to be honest, I think the best
24 folks to be held accountable to get that market model
25 standard and more or less to make it is probably you all

1 telling us, the RTOs, you know, get a model together and
2 then make it happen. Because we're the ones who know the
3 data and we know the impact on our participants. In other
4 words, we're sort of right in the middle between the users,
5 if you will.

6 So I think it has to happen. I agree.

7 MS. SILVERSTEIN: We have painful repeated
8 experience of organizations composed of one group of players
9 within the market, and I don't mean to say that ISOs and
10 RTOs are just another player, but, you know, trust me, I'll
11 take care of you is a little nervous-making. And we would
12 want, as I think all the market participants would want to
13 be sure that when you say trust me, I'll take care of you,
14 will get us a product, a software thing that meets your
15 needs, generators, market monitors, load-serving entities.

16 I see this as being a bigger group of players at
17 the table than just RTO and ISO IT guys. Is that correct?

18 MR. WATKINS: That's I think what we were
19 thinking. You know, I don't think any of us knows the right
20 model for doing this, but I think I've heard a consistent
21 theme that says please don't tell us the data standards and
22 don't be specific on that.

23 But it seems to me I'm also hearing, and I think
24 we believe this, you need to say, establish a data standard
25 that everyone can talk to and everyone can plug their

1 modules and pieces into so there's competition on the vendor
2 end and so that everyone can play on a level playing field.

3 And then I think our thought would be, let us do
4 that. And that was the thought I think with that picture I
5 was trying to paint, which is I don't care. I really don't.
6 And I don't think our group does. What we care about is
7 there's a viable model for getting this done, and our model
8 was, in this case, vendors know all that because they're
9 putting all these systems in for us. Guide them. You know,
10 don't let them be the sealers of a standard, let them be the
11 makers of the standard and then have someone else approve it
12 and have them involved with the customers, the ISOs, the
13 merchants and so on.

14 I don't know the right model, but it seems like
15 it does need a wider group and it need something that's
16 self-motivated, that's involved with knowing the technical
17 details of it.

18 MR. PALIZA: Talking about pain, I think, you
19 know, I think it needs to be emphasized the need for these
20 standards to change the models. These markets are based on
21 State Estimator models, State Estimator solutions.

22 Right now the Midwest ISO is trying to put
23 together one of the largest State Estimation processes in
24 the Eastern Interconnection, and we have to deal with Vendor
25 A, Vendor B model, Vendor C model, you know, and trying to

1 make them compatible so that we can merge these models. And
2 the impact on that is, there is a significant effort in
3 converting these models and make them compatible and
4 eventually merge them into a model that we need.

5 So there is an expense, a significant expense
6 that industry is paying for not having these standards. I
7 took Jay's comment to mean that there should be I think
8 there is going to be definitely in this effort of the
9 standard market implementation a short-term goal and a long-
10 term goal. We're trying to get there as soon as we can with
11 the tools that we have and the resources that are available,
12 but at the same time, we shouldn't lose sight of where we
13 should be going, you know, five years out there.

1 MR. FINNEY: Personally, you know, I do like the
2 CIM even if it's not specified explicitly, if for no other
3 reason than it is a standard, it is big, and it is working.
4 So it is a good place to extend as any.

5 My expectation for the NOPR in this area is I
6 would like to see standards at least asked for or required
7 in three different areas explicitly.

8 One is for exchange of data between the RTOs,
9 which we heard 30 minutes ago. Also, to standardize the
10 data access from the market participants.

11 Here again, the RTOs here have done a great job
12 of making their data available through applications such as
13 E-Suites, for example, but there has been no real effort to
14 make sure that the way it is done in Market A is the same
15 way it is done in Market B.

16 And the third helps break down that incumbent's
17 advantage that you mentioned, which is to require standards
18 for data transfer, API interoperability, between the
19 components inside.

20 Those are three very distinct areas.

21 MS. SILVERSTEIN: Between the components inside,
22 do you mean from module to module to module?

23 MR. FINNEY: Exactly. A silly analogy is pretend
24 there was a natural monopoly in baking bread. It may be
25 cheaper in incremental update to build a combination

1 oven/bread slicer that meets scope and gets that done
2 quickly.

3 But if while you do that you are not forced to
4 specify what is the interface between an oven and a bread
5 slicer, then you can get FAA legacy software propagating
6 forward throughout time.

7 So the introduction of standards can actually
8 slow us down, right, a little bit with long-term benefits
9 that allow us to have swappable components.

10 MR. BRITTON: I want to go back to my previous
11 point and earlier presentation, which is prioritize and make
12 sure of the cost/benefit cases. You should not treat data
13 standard as one thing, at the very, very least.

14 I think the focus from the discussions has by and
15 large been on model exchange as the highest priority area.
16 I totally support that. And it is also, by the way, the
17 place where CIM is at least an 80 percent proven commodity.
18 There have been vendor-to-vendor exchanges successfully done
19 via the CIM.

20 You cannot really say that very much about other
21 aspects of it.

22 But even in that area, we should recognize that
23 there are a couple of different problems. One of them is
24 exchange of whole models, which is what the CIM has been
25 used for so far.

1 The other is the process of maintaining models.
2 Now I personally believe, and I think others that I've
3 talked to that really looked at this problem go in the
4 direction that exchanging whole models is not the way that
5 you're going to maintain models in the long run.

6 What you want to do is get change reports up from
7 the sources of the information. Those are the owners and
8 operators of the transmission system. They are not even the
9 same people that you typically get the original
10 contributions of models from to build your first model.

11 In fact, getting switched over to that process is
12 kind of important because the initial models that get
13 created probably don't have the quality they could have if
14 they had been able to go to all the original sources of
15 data. That just wasn't practical in getting things
16 initialized.

17 So we have got one part of the problem that we're
18 close to a solution on, and another part of the problem that
19 really hasn't been well addressed yet.

20 We need to understand that this whole area of
21 data standards is like that. There are compartments that
22 are relatively easy to approach and compartments that are
23 not, and we are going to have to have a process that works
24 with that.

25 MS. SILVERSTEIN: Let me very quickly thank all

1 of you for being very good at using your microphones, but I
2 wanted to ask you to do one more thing. Readjust your name
3 tags and your water bottle to make sure that they're facing
4 that lady right there so that she knows who you are and who
5 is talking.

6 Thank you, very much.

7 So let me just make sure. You all are pretty
8 much inviting us to tell you to standardize something, and
9 we're starting with the data.

10 I wanted to ask you a follow-up question about
11 that. That is, in terms of timing if for the sake of
12 argument the draft NOPR, the Notice of Proposed Rulemaking
13 that comes out in two weeks says please standardize. Chat
14 amongst yourselves. Develop a group. Develop a process.
15 Start data standardization.

16 Is an invitation and a NOPR good enough for ya'll
17 to start organizing yourselves? Do you need additional
18 support and facilitation from us to get this started in
19 August or September instead of waiting until the final rule
20 comes out in December?

21 MR. THOMPSON: I was going to suggest, I mean
22 this is certainly a process everybody recognizes the
23 benefits of, but it's going to be a difficult process.

24 There are a couple of models for this. The CIM,
25 development of the CIM model was one. The electronic

1 tagging effort, et cetera. These are not simple processes
2 at all.

3 I think that maybe one of the things that should
4 be--that this topic ought to be a subject of one of your, of
5 the workshops that you are planning to have here after you
6 release the NOPR to try to develop a plan for how to go
7 about getting this done, and getting it done in a time frame
8 where we're not going to spend the next three or four years
9 waiting to see how the standards turn out.

10 And at the same time, we are trying to develop
11 approaches to meeting the other requirements in a system
12 software implementation of the SMD.

13 MS. SILVERSTEIN: So ya'll should set aside a day
14 in September, then, because we will be doing that very
15 thing. That conference will be on the topic of data
16 standardization.

17 You notice I like to close the deal right away?

18 The next deal I want to know whether we're
19 looking at is what else do you want us to be inviting you to
20 standardize in the NOPR? Make us an offer. Oh, you're the
21 one.

22 MR. O'NEILL: How about test data sets,
23 benchmarking problems, things like that? Can the group get
24 together and put together a set of test problems so that
25 people can compare their algorithmic development and

1 essentially just have standardized ways of bragging about
2 doing business?

3 MR. THOMPSON: Well, I think maybe one of the
4 initial parts of that ought to be the definition of what
5 particular aspects really need to have benchmarks
6 established for them. Because there--

7 MR. O'NEILL: Can I have your proxy, Andy?

8 (Laughter.)

9 (Mr. Ott leaves.)

10 MR. THOMPSON: What are the specific areas of the
11 Standard Market Design that need to be benchmarked, and for
12 what? It would be, I would suggest, one of the first
13 subjects there that needs to be understood.

14 MR. O'NEILL: Certainly--well I mean you can just
15 rattle off certainly the State Estimator. It would be nice
16 to have some State Estimator data sets.

17 Certainly the Unit Commitment problem. You
18 yourself said that you were starting to get backed up with
19 all the passes through the Unit Commitment. There are
20 people who are working on that on a regular basis.

21 And our suggestion that option rights be included
22 in the Standard Transmission Rights proposal raised a lot of
23 at least hand wringing on whether or not they were
24 computable.

25 Now people are claiming, yes, they have solved

1 these problems. That they can hardly press the enter button
2 before the problems get solved. But we're not sure exactly
3 what they're solving. And what we need to do is to say,
4 okay, here is the problem that is recognized as a difficult
5 problem because PJM, or New York, or PJM-MISO and SPP get
6 together and say here is a hard problem. And then people
7 can go to work on it and they can tell us: We solved this
8 problem. We did it this fast. Here's the value of the, the
9 total bid value that we maximized so that we can get a
10 measure of how good the software was. And we know what you
11 have.

12 Right now when we talk to people, they all make
13 wonderful claims and I tend to believe them, but I don't
14 know exactly how to compare the claims.

15 MR. FINNEY: I support it. That's easy for me
16 because I'm on the vendor side and this is the type of thing
17 that we like to do.

18 I would like to hear from the RTO participants,
19 you know, what level of priority they would place upon this.

20 MS. SILVERSTEIN: Mr. Britton has been waiting
21 for a couple of minutes. We'll go to him first.

22 MR. BRITTON: I support the benchmark initiative.
23 I do think clean problems are a key, and those need to come
24 from real systems to be very meaningful. So I really echo
25 what John said. It's the ISO/RTO community that needs to be

1 in this.

2 MR. LA PLANTE: Yes. We would support that also.

3 There's also I think an assumption involved with doing that,
4 which is that the software that's doing it is in fact
5 consistent with the Standard Market Design, and whether or
6 not we may need a separate process or a separate effort to
7 actually certify that the software is solving the right
8 problem.

9 So that is sort of hidden. Before we get there,
10 we have to understand that and make sure of that.

11 MS. SILVERSTEIN: I was promised this morning
12 that if the software gave you a result that didn't match
13 reality, you just needed rules to manage around that.

14 MR. LA PLANTE: Well you could do both. You
15 could do it either way, but you've got to pick a way.

16 (Laughter.)

17 MS. SILVERSTEIN: Is there any objection within
18 this community to doing benchmark data sets on test
19 problems?

20 MR. ALSAC: One issue will be what will be the
21 format of these benchmarks. Because we can create a
22 benchmark format which is not going to be standard format
23 and then we will be having now two formats.

24 So I think first the format we have to create,
25 and then the test systems. We can do both simultaneously,

1 but they have to be very correlated.

2 MS. SILVERSTEIN: My suspicion is there might be
3 a little bit of a chicken and egg problem here and we can
4 put the entire food chain together by having the folks who
5 do this, the data standardization design the test problem
6 and make it somewhat referential in terms of test-out, do
7 your data standards work by designing your data--your
8 problem.

9 MR. ALSAC: That will work.

10 Another point I have is that there are two kinds
11 of data. One is like interchange of data between ISOs or
12 between vendors, and that is very detailed data. Another
13 data is data provided to participants. And as Andy says,
14 ISOs have these very detailed models.

15 But participants don't have State Estimators,
16 topology problems, nothing. So we have to separate these
17 two issues.

18 What do we provide to the participants so that
19 they can handle that data and use their stand-alone tools to
20 very quickly absorb it to their own systems?

21 And then what is the much more detailed models
22 which ISOs interchange vendors use.

23 So there are two separate. One is more important
24 maybe, but if we are going to train participants, the data
25 for participants is extremely critical.

1 MS. SILVERSTEIN: I suspect that if we make it
2 clear that we would like participants to participate in the
3 data standardization process by telling us what data they
4 want and need, that they would be more than happy to show up
5 and we can use our friends at the trade associations to make
6 sure that they show. Yes?

7 MR. WATKINS: I don't know the answer, but it
8 seems to me, I'm not sure what benefit you gain from doing
9 standard benchmarks when you define the function itself.
10 Each RTO or ISO has a very complex set of models that they
11 have to employ anyway and do extensive testing on, and they
12 have to do that. They have to do it on their data, on their
13 market system.

14 So it is an interesting thing maybe to learn how
15 someone's system performed against another on a standard
16 benchmark, maybe, but--and that might be the right thing.
17 My only question is: Is that a useful activity in the time
18 it takes to develop such things compared to the real work we
19 have at hand?

20 That is the only question I would ask.

21 MS. SILVERSTEIN: Why don't we put the issue of
22 benchmark data sets which clearly the vendors are more
23 enamored of than perhaps the ISOs are, why don't we put that
24 question aside to discuss at our September workshop, where
25 we'll hope to see you all again, on the matter of data

1 standardization. We will commit an hour or two to discuss
2 the: Do we need to do benchmarking of data, as well, a
3 common data problem?

4 The next question is: If we need a standards
5 organization, to what degree does--and I'm hearing you all
6 want one--to what degree does, how detailed an intervention
7 does FERC have to get to make that happen?

8 We have models like NASB, like the Coalition For
9 Uniform Business Rules, EPRI has initiated some work, IEEE
10 has done some. Do we need to say you've got to do it and it
11 looks like this? Or do we just stand back and say please
12 make it happen and see what ya'll toss back at us?

13 MR. LA PLANTE: Are you talking about data
14 standards now? Or rules, business rules? Or interpreting
15 the Standard Market Design standards? If a change is needed
16 to the Standard Market Design, that thing? Or is this more
17 on a higher--

18 MS. SILVERSTEIN: Well, we have this gruesome
19 process called regulation and comments and cases, which is
20 where people tell us they want changes to the Standard
21 Market Design.

22 I was thinking more of the kind of entity that
23 one of you was talking about, a technical--maybe it was
24 ERCOT; I don't know who it was--but there are tech work
25 groups that sort of mastermind the implementation and decide

1 in common if there's some ambiguity, this is how we're going
2 to agree to interpret it?

3 MR. RISTANOVIC: It all depends on the goal,
4 because time is very short. If we don't standardize
5 components and data modeling in the next two or three
6 months, so many systems will start without standards and it
7 will be no point doing it later, because they will go
8 regular way. All them will be customized, difficult to
9 change. The same market design, but each of them would be
10 one-of-a-kind and you don't have competition. You have high
11 prices. You have expensive testing and re-testing and
12 expensive maintenance.

13 In standardization bodies where you have no
14 strong hand, it usually takes a very, very long time to
15 standardize anything.

16 We are very close to standardize what is needed
17 to support energy market. CIM has a lot that we need for
18 energy markets. But there is very little missing. What we
19 need? We need strong FERC involvement. We need FERC to get
20 requirements quickly for vendors and other interested
21 parties, to hire some for-profit organization to standardize
22 components, to standardize extensions on CIM; that for-
23 profit organization to report back to FERC.

24 We can all comment to that, and quickly come up
25 with something. That is important for all the systems

1 coming up in the next five to six months, CTRANS, Northeast
2 RTO, Midwest ISO, everybody. If we don't do it in the next
3 three to six months, it is going to be late for most of
4 these systems.

5 I hear also the discussion about priorities. We
6 are talking about priorities for something I call peanuts.
7 When you think about templates for OASIS which are similar
8 to what you're talking about front end for market portals,
9 we're talking about relatively small amount of data and
10 interfaces for market participants.

11 The benefit of that, yes, is huge for visibility
12 for market participants, but impact on the cost of building
13 RTOs and maintaining RTOs is almost nonexistent. Because
14 you have to maintain binary interfaces, and every time you
15 change something you have to support all the interfaces.

16 So market participant says I don't want to switch
17 to new interface, I want to use the old one. So you have to
18 give them the capability.

19 My point is that we are very close, and if you
20 want to have competition, if you want to have a lower cost
21 of testing and building system and maintaining it, it is
22 time that FERC has to be very active.

23 Later, once this process, like speed-up process
24 is moved and some organization like KEMA can be for
25 nonprofit organization or has enough knowledge to speed up

1 this first step, we can push further. We can send it to
2 EPRI, go through IC Rule 13, make it international standard,
3 because that's kind of slow process but it's still good
4 because it can expand this worldwide.

5 Because what we are doing here, everybody
6 worldwide is going to be watching soon. And if you don't
7 standardize, nobody will standardize. And this mushroom of
8 cost, which looks good for vendors but believe me is not
9 good, is going to propagate worldwide.

10 So it is very important to act quickly.

11 MR. BRITTON: I go along with what Petar said in
12 at least one thing. That is, we should get a standards
13 process in place quickly.

14 I am operating under the presumption here that at
15 least some items are going to be the subject of standards
16 and need a standards body with a good process. And in that
17 regard, the two really important things are a neutral forum
18 for discussion and somebody with a proven process.

19 Because the process itself takes a while to
20 wrangle out, if you just throw a bunch of people in a room
21 and have them start at it.

22 So if you look at a model like an OMG or
23 something like that, they've got a very well established
24 process. It is valuable--I'm not suggesting that as an
25 organization here, but you want to hook up with somebody who

1 already knows how to vote, and how to decide on who wins if
2 there's contention, and all those kinds of things.

1 I don't go along with Peter's assessment of the
2 CIM and how close it is, and I also have a feeling I'd
3 probably differ with him about exactly where the placement
4 of standards would be most useful, but, you know, what I
5 want to urge is that we get into a dialogue within the
6 standards process where we can get down to more of the
7 issues of the practicality of standardizing in one way or
8 another and in one portion or another.

9 I don't think we're going to get a good
10 discussion of those issues in this kind of a higher level
11 forum.

12 MS. SILVERSTEIN: That may be true, but it's not
13 a bad start.

14 MR. BRITTON: It's a start, yes.

15 MS. SILVERSTEIN: Anyone else?

16 DR. IRISARRI: I think it is fundamental at this
17 point in time to fully specify the interfaces, the external
18 interfaces into the RTO systems. I disagree with the need
19 to fully specify the data model that is used by Vendor A,
20 Vendor B, Vendor C, or even the technology necessary to
21 implement that data model.

22 If you have a very clear specification of what
23 data is needed, at what frequency should it be provided, in
24 what form that it can be provided, and, similarly, a very
25 clear specification on how to extract data out to market

1 participants and other RTOs or any other organizations,
2 including market monitors, that is a very step forward.

3 Let us, the rest of the developers, decide on how
4 and whether we are going to implement this model, whether we
5 are going to use CIM, if it is appropriate for the task, or
6 any other of the standards that are being offered in the
7 market at the moment.

8 MR. LaPLANTE: It seems to me that there are two
9 different things: A standardized and an open system. I
10 think that in the short term, you can open -- any vendor can
11 open on a system so everybody can look at it and develop
12 another way. In the meantime, then we can develop the
13 standard, go develop the standard which will take a long
14 time, and I don't know how long it took EPRI to develop the
15 seam. And the way that you are talking about is open
16 system, and Jay talked about that before. You know, in a
17 short time right now, we don't have a lot of ties, so if
18 vendors would open their system and document it to show what
19 is -- you want to get it out from my system, this is the way
20 to get it out and doing that.

21 And then maybe develop the standard along the
22 way, but develop the standard take a long time to develop
23 the standard, that's what I got, right?

24 MR. FINNEY: I agree that that helps expedite the
25 schedule, but requiring open system, open components without

1 standards results in systems that are not open, because if I
2 am a boutique shop trying to penetrate a market and I have
3 to write a piece of software, I have to decide, unless I
4 already have a contract to deliver, which of the five
5 systems out there I'm going to adhere to.

6 So an initial approach to require open systems
7 has to be followed almost immediately by the standards to
8 associate. Otherwise, it's a wish that cannot become a
9 reality.

10 MR. BRITTON: I don't think that's quite true. I
11 think this is sort of analogous to having different import
12 front ends on your wordprocessor as the way the world was
13 before Microsoft took it over, you know.

14 And you can cope quite well adapting, putting a
15 layer that goes to System A, and another layer that goes to
16 System B, in most cases. Now, it's not universally true,
17 but I think that in most cases, it's true.

18 The other comment that I wanted to go back to on
19 the open issue is open -- with regard to getting data, I
20 mean, I have just been involved in this same process that
21 Roberta was talking about earlier, trying to put a model
22 together.

23 And although common standards would be nice in
24 the format, the biggest obstacle is access to the data. And
25 if we had gotten access to the data, we've got lots of

1 clever programmers who can get it out and get it into the
2 right forms.

3 In the initial data preparation stage of a
4 system, you don't have to write perfect software to do
5 perfect transformations. You only have to write 95 percent,
6 and you'd be surprised how much easier it is to write 95
7 percent code.

8 You can get most of the information translated
9 with code, and the rest, you can fix up manually or any
10 other method you can figure out, and you wind up using
11 spreadsheets and lots of different little tools to work the
12 data.

13 Because it's a one-time preparation problem,
14 access to the data is the number one problem.

15 MS. SILVERSTEIN: I'd like to close this out with
16 two more things: And the first is to ask those of you who
17 are sitting at the table if you have any additional
18 information, short pieces of information or requests or
19 directions to give us, none of which, I hope, will address
20 pending cases.

21 And the second is to invite those of you in the
22 audience to either ask questions of the folks who are
23 sitting here, or to offer us on the FERC Staff, your views.
24 So let's start by whether any of you here at the table have
25 any last pieces of wisdom or requests that you want to give

1 us.

2 MR. ALSAC: This may sound a bit strange, but
3 please give us more time, and let us know, beforehand,
4 requirements, so that we can come here better prepared,
5 addressing what you really need to discuss.

6 MS. SILVERSTEIN: You all did very nicely today.
7 Thank you.

8 MR. LaPLANTE: There was a point made earlier
9 this morning that the financial models don't need to be as
10 accurate or as precise as the physical models. It's been
11 our experience that if the financial and physical don't tie
12 out, and if the financial isn't based on what really
13 happened in reality, the market participants get very upset.

14 So you really do need to have them matched as
15 closely as possible. We can't really cheat on the financial
16 side.

17 MS. SILVERSTEIN: Anyone from the audience who
18 wants to come on up to a microphone and tell us what you
19 think or ask a question?

20 MR. AVNAESH JAYANTILAL: I agree with standards,
21 but with most financial markets, your products change over
22 time. So remember they are not going to be static
23 standards. The group must go with dynamic change as you
24 move forward. Look at PJM, for instance, look how they
25 grew. It was not a bang; it was all in one.

1 So remember that when you create a standard, it
2 should not be a static standard.

3 MS. SILVERSTEIN: Thank you. Yes, sir?

4 MR. MITCHELL: Gary Mitchell of the SPI Group.
5 We have the retail hub in Ontario. I'm just wondering if
6 anybody has really looked at the open system, the standards
7 that are on the Ontario Energy Board website? That's been
8 used in Ontario.

9 Right now, there are three hubs active in
10 Ontario. They communicate with each other. Myself, we're
11 the largest vendor out there, but we have over 20 CIS
12 systems hooked up to our system right now.

13 Our output is, we have about 20-percent switch-
14 over rate since the market opened. That's on the retail
15 side. Our standard is very strong. It's XML-based; it's
16 schema-based, multi-schemas.

17 I just want you to actually take a look at what
18 the regulator has done there. There are a lot of issues
19 that were brought up today that have been resolved in
20 Ontario, have been discussed in Ontario.

21 Some of the things, for example, in Ontario,
22 there was not an ISO that built the retail system; it was
23 private companies that actually built it. We were put into
24 a room for two years to build that standard that's sitting
25 on the OEB website.

1 We had to give it to them, once we were done.
2 That's the one that sits there. After the market is open --
3 prior to market opening, we had a working group. The
4 working group was with four different vendors, plus I think
5 it was three large LDCs and one retailer. After the market,
6 now there's about 25 people in the working group.

7 They're all working together to get this
8 resolved. The market is working very well there. The
9 systems are very active, my market itself, with six million
10 transactions since market opened. So, there are systems out
11 there that do work; there are standards that are already out
12 there as what was discussed here.

13 The reason why I bring this up is nobody has
14 talked about the Ontario market, and it is something that
15 should really be looked at.

16 MS. SILVERSTEIN: Thank you very much. So, we'd
17 like to plagiarize from the best, and we also would like to
18 use strawmen to move things along faster, rather than
19 starting from scratch, so a homework assignment for you all
20 before our September workshop is to -- can you come back,
21 Gary, and tell us the website to go looking at?

22 MR. MITCHELL: It's www.oeb.gov.on.ca.

23 MS. SILVERSTEIN: www.oeb.gov.on.ca?

24 MR. MITCHELL: Right.

25 MS. SILVERSTEIN: So --

1 MR. MITCHELL: And it's the EBT standards that
2 are sitting there. There has been quite a bit of work done
3 on it already. Like I said, it is a system that's working.
4 We have resolved a lot of the issues that are happening
5 within Texas and such right now, with switch-overs and stuff
6 like that. The system is working fairly strong there right
7 now.

8 MS. SILVERSTEIN: So, maybe one of the things you
9 all can be prepared to come back and talk about in September
10 is whether those are an appropriate strawman for us to build
11 on going forward. Thank you very much.

12 MR. LIVELY: My name is Mark Lively. The
13 question that I look at is how the standard market design
14 should be able to handle such issues as loop flow, and the
15 cash-out of inadvertent interchange, in that most of the
16 discussion today has been about a forwards market, as
17 opposed to a concurrent spot market for those little issues
18 of how the physics of the system works in getting the cash
19 to flow the same way the electrons flow.

20 MS. SILVERSTEIN: Is that a question for them or
21 a question for us?

22 MR. LIVELY: A question for them. Since they're
23 talking about standard market design and how to get the data
24 to work for the systems interface, the seams managements
25 between them, they need to be sure that they are collecting

1 the right data and restoring the data so that they can cash
2 out those unscheduled flows of electricity so that when
3 things like the expansion of the MISO and PJM results in
4 loop flows through TVA and the Southern Company and CP&L and
5 the companies in the South, the C-trends, how can they then
6 cash that out, and how they can have data systems in place
7 and operating systems in place to provide that cash-out.

8 (No response.)

9 MS. SILVERSTEIN: Sorry, Mark, we're not hearing
10 a lot of takers for that one. Yes, sir?

11 MR. MAYER SASSON: Thank you. Mayer Sasson from
12 Con Edison in New York. Transmission owners in New York
13 feel that what will benefit the best, consumers, is to have
14 access to the largest markets possible.

15 And I think we also feel that is what is going to
16 benefit the most, the suppliers, to be able to sell into the
17 largest market possible. There are two ways we can do that:

18 One is to try to merge organizations and get the
19 biggest possible organization, with everybody inside, but
20 the other one, I think Guillermo Irisarri mentioned it
21 tangentially today, which is to have the systems in the
22 different ISOs and RTOs interoperate.

23 And that is going to require more than just data
24 exchange. We need to have coordination between the
25 solutions, for example, a unit commitment process that

1 actually solves in stages in the different areas, and then
2 somehow comes together.

3 I'm not sure if everybody is aware of this, but
4 in this room, in this longest table and with some of the
5 people that are here, there is enormous talent with 20, 30
6 years of experience in developing software tools, but not
7 the software itself, but the analytical tools necessary,
8 that I think it's a problem that we can solve if we really
9 put ourselves into doing this. So that's an idea I had not
10 heard this morning.

11 MS. SILVERSTEIN: Thank you. Any more comments,
12 suggestions, questions? Yes, we have a winner.

13 MR. BILL PETTITT: Bill Pettitt of the IMO. I
14 just wanted to make sure that this panel or this is
15 addressed -- is the market surveillance or market monitoring
16 is a big item in our systems. It's one of the most
17 difficult things to put together.

18 Of all the systems we're putting together, it's
19 not so much the EMS and the market systems, it's actually
20 the monitoring of it that's the big thing.

21 On the settlement side of things, collecting all
22 the meters is a big job, as well. When we get the -- if we
23 get a bigger RTO, collecting x-number of meters at five-
24 minute intervals, it's a challenge in itself. We have a
25 challenge in collecting the number of meters we have right

1 now.

2 And the other thing that I wanted to address was
3 the separation of the operation from actually the price end,
4 the settlement part of things. Right now, we have an
5 integrated operating system and settlement system, or
6 basically the price is computed right away, and if the price
7 isn't computed right away, it's lost.

8 But we can compute the price later, if we keep
9 that information on hand, so if we have systems that are
10 available to keep the information, price is computed after
11 the fact, not on a continuous basis, we still have a
12 dispatch being done on a continuous basis, no matter what.
13 So these two things do not need to be integrated, but they
14 are now. That might simplify things for these systems.

15 MS. SILVERSTEIN: Thank you very much. As a
16 thank you present to all of you for giving us your time and
17 your expertise, we're going to let you go half a hour early.

18

19 I found this very useful. I think the rest of
20 our staff members have, and I hope you found something in it
21 to make the trip worthwhile. Thank you so much for your
22 commitment and your participation, and we'll look forward to
23 seeing you again in a couple of months.

24 (Whereupon, at 4:25 p.m., the Conference was
25 concluded.)
